There are currently around fifty documented prehistoric sites in San Francisco. These prehistoric sites include several large settlement sites (inhabited up to 1,000 years), cemeteries, food-procurement camps, tool workshops, and historic-period Indigenous sites. One Indigenous site has been dated to nearly 6,000 years before the present and lay 75 feet below the surface. In contrast to prehistoric shell mound sites found elsewhere in the Bay Area, many shell mounds discovered in San Francisco have remarkable integrity because they have been buried for several hundred years beneath native sand dune deposits, enabling the study of their use and significance in the final periods before their abandonment. The high density and number of prehistoric sites in San Francisco provide the opportunity to study them as regional and sub-regional systems. In the light of field investigations and new theoretical approaches, it is now known the prehistory of the Bay Area was not one of slow uniform evolution but, rather, was punctuated by radical large-scale changes. The newer picture of San Francisco Bay Area prehistory indicates:

- Prehistoric sites sometimes occur in clusters with a primarily symbolic association with a focal shellmound of greater size and age
- The importance of the primary shellmound may have been in the form of religious/funerary observances and burials even after its abandonment
- Bay Area prehistoric shellmounds may have been planned, intentionally re-created structures (not merely inadvertent dietary refuse accumulations)
- Prehistoric shellmounds were sometimes constructed over pre-existing cemeteries
- Many Bay Area shell mounds were abandoned over the course of a relatively brief period

It is known that humans have been present within the urban area now known as San Francisco for at least 6,000 years and within the greater Bay Area for a period of time nearly twice as long. As prehistoric sites beneath the Bay and ocean floor or buried beneath late Holocene sand dune deposits are investigated in the future, the advent of local human prehistory may be pushed back even further in time. The earliest peoples currently known to have inhabited the San Francisco Bay Area were comprised of widespread but sparse populations of hunter-gatherers whose subsistence was based on large game, seeds, and nuts as evidenced by the presence of large projectile points and milling stones (*manos* and *metates*). These peoples lived in small nomadic bands that made less use of shoreline and wetlands resources than later prehistoric populations. Soon after 2000 B.P. (years before present), bayshore- and marsh-adapted people who were Utian language (Miwok-Costanoan language family) speaking people began to migrate into the Bay Area from the Central Valley, displacing the earlier Hokan language speaking populations. The new inhabitants were different than the older resident populations in a number of respects, including language; larger and more sedentary settlements; a subsistence based on acorns; shellfish and small game; and mortuary practices; personal ornaments; and perhaps the fabrication of coiled basketry. It is assumed that the Costanoan representatives of this Utian dispersal reached the northern end of the San Francisco peninsula no later than 500 B.C. (before Christ).

Early Holocene (11,000–8,000 B.P.)

There are few human sites in San Francisco Bay Area dating from this period and none have, as yet, been documented in San Francisco. Populations from this time probably lived in small groups that migrated frequently in accord with the annual patterns of preferred game and plants. Early Holocene sites may contain handstones, milling slabs, cutting and scraping tools, bifaces, dietary remains, or human burials.

Middle Holocene (8,000–4,000 B.P.)

The earliest evidence for human occupation in the San Francisco is roughly 6,000 B.P. The earlier focus on big-game hunting shifted to gathering a wider array of food resources, especially plants and seeds, during this period. Groups moved seasonally to different environments to use resources as they became available. The greater reliance on seeds is reflected in the kinds and number of artifacts recovered from sites dating to this period such as relatively large numbers of grinding tools. Investigations at sites located in Santa Clara County, indicate that during this period acorns became increasingly relied upon for food. Sites dating to this period tend to be deeply buried.

Late Holocene (4,000–230 B.P.)

Nearly all the prehistoric sites discovered in San Francisco are Late Holocene sites. Almost no dating, and no definitive dating, of prehistoric sites in the Hunters Point-Bayview-Candlestick Point area has occurred. Some of the prehistoric deposits in the southeast part of San Francisco may prove to be earlier than the Middle Holocene period.

During this period, there was a general trend throughout California for groups to adapt to local environmental conditions. Shellmounds are the dominant type of site in the Bay Area that date to this interval, and over 400 shellmound sites from this period have been recorded in the Bay Area. Shellmounds are typically found near or along the open Bay and next to streams flowing into the Bay. Artifacts often found in shellmound sites include stone net sinkers used to weight nets down, mortars and pestles for

grinding seeds and other plant material, bone tools manufactured from faunal remains, rectangular shell beads, stone arrowheads, and stone knives.

Four prehistoric sites are known or believed to be located within the Project site. All are reported as likely shellmounds or shell midden (an archaeological deposit which may contain copious amounts of mollusk shell in addition to stone debris from tool manufacture, animal bone, plant material, and other artifacts associated with past human occupation). The sites were originally documented in the early 1900s; however, since that time the Project site has been extensively developed. Disturbances to natural and man-made landmarks which were used to locate the sites have vanished, and today the exact site locations are unknown.

Previous archaeological investigations in San Francisco have located large intact cultural deposits likely dating to the 4000 to 230 B.P. period. Those substantial deposits are located deep below the modern surface. It is possible that conditions are similar in the Project site. It is, therefore, likely that some significant portion(s) of the four sites known or thought to be within the Project site are located deep beneath the present ground surface. It is also possible that an undiscovered prehistoric site could be encountered during Project-related construction activities. The last interval (post 230 B.P.) is considered the ethnographic period and is discussed below.

Indigenous Peoples: the Ethnohistorical Record

Attempts to understand indigenous peoples and reconstruct their way of life scientifically and interpretively through the written, cartographic, and pictorial documentary record provides a relatively reliable knowledge of indigenous peoples from the late Holocene Period to the present. To an important extent, this documentary record is based on recorded late nineteenth and early twentieth century "reminiscence" accounts of indigenous existence prior to the late eighteenth century missionization in the Bay Area.

Ethnography

The Project site lies within the traditional territory of the indigenous Ohlone (Costanoan) people. The northern tip of the San Francisco peninsula was once within the *Yelamu* tribal territory.[236] The *Yelamu* were one of a number of smaller tribal groups within the larger Ohlone language family. At the time of European contact, Ohlone lived in extended families which traced descent through the male line. Families were organized into clans, and they in turn essentially divided all members of the social structure into one of two groups—in this case the Bear and the Deer.

The staple food for the Ohlone people in the Bay Area was the acorn. Acorns were pounded into flour using a stone mortar and pestle, leached of tannic acids, and made into a mush or bread. Buckeye was also eaten and prepared similarly to acorns. Other plant species that were used include a variety of berries, roots, shoots, and seeds from wild onion, cattail, wild carrot, tarweed, chia, and many others. Controlled burning of land was practiced to help ensure future wild plant harvests. Clams, ocean and bay mussels, and oysters were also important components of the diet. Other sources of protein included various game birds, waterfowl, and large terrestrial and sea mammals.

[236] Milliken, Randall T. *A Time of Little Choice: the Disintegration of Tribal Culture in the San Francisco Bay Area, 1769–1810*, (Ramona: Ballena Press, 1995), 61.

Tules were used for material to make structures and watercraft. Balsa canoes were used to hunt waterfowl, fishing, and probably hunting sea mammals. Canoes were also used for travel and trade across the Bay and salt marshes. Fiber from plants were used to make a variety of basketry forms including cooking containers, utensils, storage containers, seed beaters, water jugs, cradles, fish traps, and burden baskets. Animal bones were used to make awls, pins, daggers, scrapers, knives, and other tools. Pelts and feathers were used for clothing, sinew for bows, and feather, bone, and shell for several different kinds of ornamentation including beads, pendants, hair bangles, septum inserts, and earrings. Local and imported stone and minerals were used to make a large number of tools. Local commodities used in trade included cinnabar (red mercury sulfide or native vermillion), hematite (the mineral form of an iron oxide), salt, shellfish meat, and shell for ornament manufacture.

As noted above, the Costanoan tribe that occupied the northern end of the San Francisco peninsula in the late eighteenth century is known under the general term *Yelamu*. The *Yelamu* were divided into three semi sedentary village groups. The *Yelamu* were composed of at least five settlements (*Chutchi*, *Sitlintac*, *Amuctac*, *Tubsinte*, and *Petlenuc*) that were located within present day San Francisco. *Yelamu* may have also been the name of an additional settlement within the vicinity of Mission Dolores. *Sitlintac* may have been located on the Bay shore near the large tidal wetlands of the Mission Creek estuary. *Chutchui* was located near the lake (*Laguna de los Dolores*) east of the current Mission Dolores, two to three miles in-land. These two villages were probably the seasonally settlements of one band of the *Yelamu* who used them alternately. Another *Yelamu* band seasonally used the village sites of *Amuctac* and *Tubsinte* that were located in Visitation Valley. *Tubsinte* may prove to be identified with CA-SFR-7, west of Candlestick Point, or the Ralston Mound, in Visitation Valley. No late period deposits have been investigated at CA-SFR-7 and the Ralston Mound has not been scientifically field investigated. A third *Yelamu* band, the *Petlenuc*, may have had a small settlement near the Presidio. The *Yelamu* were allied by marriage to Costanoan groups on the east side of San Francisco Bay.

Within less than two months after the Spanish began construction of the first Mission Dolores in 1776, all of the *Yelamu* villages in San Francisco were attacked and burned by an expedition sent by the *Ssalson* tribe, the Costanoan tribe of the San Mateo area. The *Yelamu* survivors abandoned all of the San Francisco settlements, seeking refuge with other groups in the East Bay and Marin. Until they were missionized in the late eighteenth century, the *Yelamu* only returned to San Francisco for occasional hunting. Prehistoric Costanoan and/or pre-Costanoan peoples may have maintained settlements or specialized activity sites (shellfish processing, hunting blind, ritual, burial sites) within the Project Area.

Historic Context

Overview

No occupation or use of the area within the Project site has been documented for the Hispanic and Early American Periods (1776–1848). However with the initiation of the Gold Rush in 1849 and subsequent statehood a year later, San Francisco's population and geographic area grew rapidly over a short period of time. The area around the entrance to San Francisco Bay was planned for more intensive development while the Bayview-Hunters Point area remained primarily pasture land.

Settlement in the Project vicinity during the 1850s and 1860s was primarily limited to the area just north of the Project site in India Basin, where northern European boat builders established small family

boatyards. From the 1880s through 1910, this area was the center of design and construction of scow schooners of which the Bay Area scow schooner represents a specialized region type. Drydock development (an uncommon ship construction facility type in San Francisco) also began by the late 1860s and continued until the early 1900s.

On Hunters Point, Italian and Chinese farmers moved into the area to grow vegetables for the growing City center located four miles to the north. Known as "truck farming," these agriculturalists grew fruit and vegetables on small plots of land and then carted their product to the urban markets to sell. By the turn of the century, the Italians dominated this industry, but as the century progressed agricultural endeavors within the area began to decline. The Chinese also began to establish fish and shrimp farms along the Hunters Point; these will be discussed in more detail in the Historic Context Themes section.

Some progress toward attracting further settlement was achieved with the construction of the Bay View Park racetrack in 1863 and Long Bridge in 1865.[237] Despite this an overall lack of established roads, access to the interior of the Project site remained difficult in the early years of settlement. Nevertheless, favorable weather and fresh water access enticed real estate speculators to the area during the 1860s as well.

One of the earliest real estate partnerships was between Jose Bernal's family and two land speculators, John Townsend and Corneille de Boom. Townsend and de Boom convinced Bernal to subdivide the land located at Hunters Point into lots and call the new homestead "South San Francisco.[238] To sell this idea, two brothers Robert Eugene and Philip Schuyler Hunter were brought in from the east coast. Despite the abundance of underground fresh water, well-made plans, and abundant advertising, the area was simply located too far from the city center to be viable. Despite the failure of the real estate venture, The Hunter brothers (for whom the area is named) stayed at Hunters Point as a pioneering family operating dairy and gardening ventures. They also sold spring water to ships from around the world by leasing water rights to the Independent Water Company.[239] The Hunter family occupied the area until they sold it in the 1870s.

Although some further early homesteading attempts in the Project site enjoyed modest success, by the early 1900s most of the area was still fairly open. The population was still predominantly Italian, with a fair number of Irish, Maltese, Portuguese, and Chinese settlers. These ethnic groups formed small enclaves within the larger community, sponsoring their own churches and social clubs. In the aftermath of the 1906 San Francisco earthquake and fire, Hunters Point, which was spared from the worst of the disaster, became an area of respite from smoke, chaos, and debris.

The Southern Pacific Railroad finished the Bayshore Cutoff in 1908, opening a direct rail line to the area. The railroad eventually included a 4,110-foot bridge over Islais Creek north of Custer Streets between Islais and Tulare Streets. While general access to the area had steadily improved, there were still impediments to industrial and residential development that had yet to be adequately addressed. The biggest problem was topography.

By the mid-1920s, the character of the Project vicinity started to shift from a mix of industrial and pastoral uses to a more organized urban environment. However, the boatyards, drydocks, greenhouses, and farms in the Project vicinity continued to dominate the landscape and shape where people settled. By the 1930s, City

[237] Archeo-Tec, *Historical Context for the Archaeology of the Bayview Waterfront Project, San Francisco, California*, p. 49, 2008.

[239] Ibid, p. 44.

government officially recognized Hunters Point as a separate district. In 1939, after fighting for years for paved streets, parks, sewer-line extensions, and public transportation, residents near the India Basin boatyards formed the Hunters Point Improvement Association to achieve needed community improvements.

Just prior to World War II, the Navy contracted with the drydocks at Hunters Point. The drydocks were expanded twice in response to the Navy's shipyard needs; the drydocks were one of the Navy's primary shipyard resources on the Pacific Coast. This eventually prompted them to purchase the Union Iron Works Dry Docks from Bethlehem Steel (the parent company of Union Iron Works) in 1939.

When the United States entered World War II at the end of 1941, the Navy had just completed its takeover of the drydocks at Hunters Point. From there, construction ensued for the next five years, dramatically increasing the dry landmass around the end of the Hunters Point and changing the topography of the entire area through reclamation efforts. Demands for housing for the defense workers at the shipyard resulted in the construction of over 12,000 housing units in the immediate area. Every portion of the Project site was affected by these housing projects. The population increase transformed the rural Bayview and Hunters Point neighborhoods into an urban center almost overnight. Demographic shifts from Italian to African-American predominance, economic shifts from agriculture to heavy industry, and social shifts from multigenerational families to transient settlers, all occurred during this highly tumultuous time.

After World War II, construction continued at Hunters Point Shipyard, but the number of jobs began to decrease. A sizable peacetime workforce was needed, but not in the around-the-clock fashion that was common during the war. The decrease in work prompted some families to leave the area.

The post-war period in San Francisco was marked by an extreme shortage of quality housing, especially for the low-income segment of population. Many of the temporary housing units built by the Navy around Hunters Point became apartment units managed by the San Francisco Housing Authority, transforming the area into the highest concentration of low-income housing in San Francisco. The history of the post-war period within the Project site is largely a story of the transition of this housing stock and its impact on the more well-established surrounding community. Due to the population shift described above, African-Americans remained the dominant ethnic group in the area and the main residents of area.

Historic Context Subareas

Candlestick Point

Candlestick Point was named after the long-billed curlew, a common shorebird locally known as the Candlestick Bird. Past uses in this area have included a quarry, a landfill, and a proposed site for a quarantine hospital.

In 1910, Candlestick Point was proposed as the site of a detention hospital for quarantining people with communicable diseases. The owners of the land opposed the project, and Candlestick Point was dedicated as a public park in 1915. During World War II, housing for families called Candlestick Cove War Dwellings was constructed. In 1954, a bond measure was passed to construct a major league baseball stadium, and by 1958 Candlestick Park Stadium was under construction. It was the first baseball stadium to be constructed entirely of concrete and was designed by John Bolles. John Bolles was a prominent Bay Area modernist architect whose other noteworthy designs include the 1959 Ping Yuen Annex housing project in Chinatown, Embarcadero Park, and the Bayview/Anna C. Waden branch library on Third Street. The

stadium was finished in time for the San Francisco Giants 1959 season. The Oakland Raiders played their 1961 American Football League season at the stadium. Candlestick Park has been home to the National Football League's San Francisco 49ers since 1971. Numerous expansions and modifications have been made to the stadium since it was built.

Prior to the construction of the Alice Griffith public housing, that site was occupied by the Double Rock War Dwellings. Constructed in the 1940s to house workers at the Shipyard, the "temporary" Double Rock War Dwellings remained occupied into the 1960s. In 1962, the San Francisco Housing Authority developed the Alice Griffith public housing to replace the war dwellings. At the time, Alice Griffith was one of the few SFHA sites that accepted African-American tenants, due to a neighborhood patterns policy that only allowed those of the predominate ethnicity of the neighborhood. This form of discrimination severely limited the locations where African-Americans could live in San Francisco.

Hunters Point

Shipyard Development

In 1885, President Cleveland's administration saw San Francisco Bay as second in importance only to New York Harbor for the nation's security. This view shaped the development in the Hunters Point area for most of the twentieth century. Expansion of military facilities in San Francisco during the first half of the twentieth century included Fort Winfield Scott (1912), Crissy Army Air Station (1921), Treasure Island (1941), and Hunters Point (1941). Many more were established throughout the East Bay and North Bay regions of the San Francisco Bay Area. San Francisco served as a primary shipbuilding and supply center, as well as one of the main westward points of embarkation throughout World Wars I and II.

What would become HPS began in 1864 as the brainchild of A.W. Von Schmidt, a German engineer. He approached the South San Francisco Homestead and Railroad Company, which was formed in 1862, with the idea that a drydock in such close proximity to their land would bring industry (and workers needing housing) to the area. They readily agreed and donated ten acres. However, financing for the construction was more difficult to secure. Eventually, Von Schmidt partnered with a number of investors, including William Ralston and Lloyd Tevis, to form the California Dry Dock Company. The drydock was largely cut from solid rock at the northeastern tip of Hunters Point. When it was completed in 1868, the California Dry Dock Company was well situated, with deep water and close proximity to the thriving scow schooner boatyards at India Basin.

At Hunters Point, the California Dry Dock Company operated through the end of the nineteenth century with limited government contracts and as a repair facility for Navy ships returning from the Pacific. Around 1901, the company changed its name to the San Francisco Dry Dock Company and commenced construction of a second drydock. Completed in 1903, the facility became the most modern drydock on the Bay.

In the meantime, the Navy further solidified its relationship with the Bethlehem Steel drydocks at Hunters Point. It subsidized construction of new, larger facilities at Hunters Point in exchange for prioritized access to the privately owned site. This arrangement enabled Bethlehem Steel to construct Drydock 3 in 1918, greatly increasing the ship repair capabilities at Hunters Point.

World War II

In response to escalating hostilities in Europe in the 1930s, the Navy purchased the Bethlehem Steel drydocks at Hunters Point in 1939. Improvements included a new assembly building just south of Drydock 2, a 50-ton crane, and an 800-foot quay wall[240] as well as smaller service- buildings. These projects were still under construction when the government terminated its lease to Bethlehem Steel in October 1941. The Navy took full control of the shipyard on December 18, 1941, just 11 days after the bombing of Pearl Harbor.

HPS was rapidly expanded and developed during the first years of US involvement in World War II. Dozens of buildings were constructed for various purposes for the war effort and beyond. Between 1939 and 1945 the shipyard was expanded from 48 acres to 583 acres. This major expansion included construction of a 1,092-foot drydock (Drydock 4), three 420-foot drydocks for submarines (5, 6, and 7 near India Basin), the leveling of a good portion of Hunters Point Hill, and the construction of dozens of buildings. The resulting 8 million cubic-yards of earth was used to fill in the Bay north and south of Hunters Point to create a submarine service area and a large flat area between Hunters Point and Yosemite Creek for future development, respectively.

The first building built by the Navy in World War II was Building 231 (1942-1945), the Inside Machine Shop. Constructed in 1942 by the San Francisco-based firm of Barrett & Hilp and situated adjacent to Drydock 2, the curtain-wall building was for a brief period the only major functional shop at the Shipyard as the United States headed into the war. Building 211 was also one of the first erected by the Navy. The building was the original Shipfitters Shop and is a good representation of the typical semi-permanent, monitor-roof shop building constructed throughout the Shipyard during the World War II era. Building 224, a concrete air raid/bomb shelter building built in 1944, and later used as an annex for the NRDL, is a unique representative of its type at the Shipyard. The only building within the district completed after World War II is the Optical, Electronics and Ordnance Building, Building 253, finished in 1947 and attached to the west elevation of Building 211. This concrete frame curtain-wall building, designed for the Navy by local architect Ernest J. Kump, was a highly specific repair and research facility.

All of the construction was centered on the stated mission of HPS: "For all classes of vessels: interim docking, shaft and propeller repairs, repairs of major underwater damage; for carriers: interim overhaul of about three to four weeks comparable to overhaul by repair vessels afloat."

A numbering system was instituted during the war, and each series of numbers generally referred to a specific functional grouping of buildings (refer to Figure III.J-1 [HPS Phase II Structures]):

- 100s—Chiefly administrative buildings located near the Main Gate.
- 200s—Industrial shops and ancillary buildings
- 300s and 400s—Industrial and warehouse buildings
- 500s and 600s—Primarily residential
- 700s and 800s—Industrial support or storage buildings or Naval Radiological Defense Laboratory-related
- 900s—Officers Mess, greenhouses and garden sheds, a bank and garage facilities

[240] A quay wall is a wharf or bank that is constructed to accommodate the loading of ships and other vessels.

Candlestick Point — Hunters Point Shipyard Phase II EIR

HPS PHASE II STRUCTURES

FIGURE III.J-1

Buildings and docks remaining on HPS include:

- Building 101—Main Administration Building, Civilian Cafeteria
- Building 103—Submarine Barracks, Personnel Decontamination Center for Operation Crossroads
- Building 104—US Naval Reserve Training Center, Naval Reserve Armory, Submarine Barracks
- Building 109—Lincoln Restaurant; HPSY Police Station
- Building 110—Marine Barracks & Mess
- Building 113—Torpedo Storage & Overhaul/Tug Maintenance, non-destructive testing
- Building 115—"US Naval Reserve Drill Hall"; Submarine Training School
- Building 116—Submarine Applied Training School, Submarine Subsistence
- Building 117—Submarine Barracks
- Building 120—Canteen, Enlisted Men's Club
- Building 121—Submarine Offices, Apprentice School, Submarine Repair Shop, Administration building, Civilian Training Center
- Building 122—Substation "V" and Compressor Plant
- Building 123—Battery Overhaul & Storage; Substation "T"
- Building 125—"Submarine Cafeteria"
- Building 128—Substation "U", Work Control Center #1, Shop Services, Ship Repair Shop
- Building 129—Administration Building, Substation "U," Submarine Pier Office
- Building 130—Pipefitter's Shop, Shipbuilding & Repair Shop
- Building 132—Submarine Pier Office, Substation "U-1," Tug Crew Barracks
- Building 134—Outside Machine Shop, Diesel Overhaul, Quality Assurance Offices
- Building 135—Substation "G"
- Building 140—Pumphouse #3
- Building 146—Industrial Photo& Laboratory Building, Electronics Repair & Storage
- Building 154—Area time office #1, Administration Building
- Building 156—Rubber Shop, Pipefitters Shop Annex
- Building 159—Latrine
- Building 203—Powerplant—Substation "H", Oil fired heating plant, CROSSROADS ship fuel burn
- Building 204—Gate and Pump House, Salt Water Pumphouse
- Building 205—Drydock 2, Pump House, Compressor House, Substation "C"
- Building 206—Substation "A" & Compressors
- Building 207—Latrine
- Building 208—Self Service Canteen and Tool Room, Shop Service Building & Tug Parts
- Building 211—Electric Shop, Machinery & Electric Test and Repairs
- Building 214—Accounting and Bond Office, Admin. Annex, Radiography, Combat Weapons Systems Office, Cafeteria facilities
- Building 215—Fire Station #1/Hunters Point Fire Department
- Building 217—Sheet Metal Shop & Ship Repair Shop
- Building 218—Latrine
- Building 219—Substation "E"
- Building 224—Air raid shelter, NRDK Annex K
- Building 225—Shop Service Building, Work Control Center #2
- Building 226—Latrine
- Building 228—Central Cafeteria/Civilian Cafeteria

- Building 229—Substation "L"
- Building 230—Shop Service building, Machine Shop
- Building 231—Inside Machine Shop, Ship Repair Shop
- Building 236—Salt Water Pump House
- Building 238—office building on the North Pier
- Building 241—Boilermakers & Blacksmiths' Shop, Forge Shop, Ship Repair Shop
- Building 251—Storage & Issue Building, Electricians' Shop, Central Tool Room, Sheet metal shop
- Building 252—Bus Terminal, Golden Anchor Coffee Shop
- Building 253—Optical, Electronics and Ordnance Building; Optical, Ordnance & Radio Shop; Maritime Administration Ships Pars Storage; Radiography; Weapon/Electronics Shop; RADIAC; Instrument Calibration Laboratory; Storage of Parts from OPERATION CROSSROADS Ships
- Building 258—Pipefitter's Shop
- Building 271—Paint Shop Annex, Equipment Storage, Sandblast Facility, Paint Lab
- Building 272—Riggers & Laborers Shop
- Building 274—Decontamination Training Building, Office Space
- Building 275—Sheet Metal Annex,
- Building 280—Covered Sheet Metal Work Area
- Building 281—Electronics, Weapons, Precision Facility/Antenna Repair
- Building 282—Antenna Abrasive Cleaning Unit
- Building 300—Substation "N"
- Building 301—Latrine
- Building 302—Transportation Shop, Automotive Vehicle Maintenance Facility
- Building 303—Transportation Shop Annex
- Building 304—Service/Gas Station
- Building 306/306A—Substation "I"
- Building 307—Electronic Storage, Public Works Equipment Storage, Electronic Assembly
- Building 308—Salt Water Pump House, Fire Protection Pumping Station
- Building 323—Boat Shop, Shore Activities/Electronics
- Building 324—CO2 Refilling Station
- Building 351/351A—NRDL Annex E, Electronics Shop, Chemical Technical Development Branch, General Research Lab
- Building 360—Test building
- Building 363—Shipwrights & Joiners Shop, Woodworkers Shop
- Building 366—Boat Shop/Plastic Shop, NRDL Electronics Work Area, Radiography Shop, Chemical Research Lab
- Building 367—Work Control Center #3, Administration Building, Field Office
- Building 368—Shop Service Building #1 Ship Repair Shop and Pipefitting Shop
- Building 369—Shop Service Building #2 Ship Repair Shop and Pipefitting Shop
- Building 370—Latrine
- Building 371—Transportation Shop Annex, Automotive Shop Building
- Building 377—Work Shop & Poseidon Systems Test Engineering
- Building 378—Latrine
- Building 379—Instrumentation/Control—Poseidon Engineering
- Building 380—Work Shop & Poseidon Systems Test Engineering
- Building 381—Shock Test Facility

- Building 383—Poseidon Shipping and Receiving
- Building 384—Poseidon Engineering
- Building 385—Poseidon Engineering
- Buildings 400, 402, 404, 405, 406, and 407—Supply storehouses
- Building 401—Building trades shop/general warehouse, Public Works Shop
- Building 409/409A—Welder Motor Generator Building
- Building 410—Welder Motor Generator Building
- Building 411—Shipfitters, Welders & Boilermakers Shop; Ship Repair Shop; Civilian Cafeteria; Radiography
- Building 412—R.R. Scales
- Building 413—Supply storehouse, Cable storage building
- Building 414—Supply storehouse, Mold loft, radium storage area
- Building 415/416—Supply storehouse
- Building 417—Acetylene Manifolding Building
- Building 418—Metal Spray Building
- Building 419—Oxygen Converter
- Building 420—Oxygen Cylinder Charging
- Building 424—Area Time Office #4, Administration Building
- Building 435—Equipment Storage, General Warehouse
- Building 436—Paint & lumber storage
- Building 437—Pipe Storage, General Warehouse
- Building 439—Equipment Storage, Sheet Metal Shop
- Building 500—Barracks, Ship Officers' Bachelors Quarters, Ships Canteen, Laundry, NRDL Admin. Offices
- Building 505—Navy Exchange Building, Gymnasium, bowling alley, and canteen
- Building 521—Power Plant—South Area
- Building 523—Fire Protection Pump Station, Salt Water pump house
- Building 525—Pacific Reserve Fleet Supply Building
- Building 526—Pacific Reserve Fleet Repair Shop
- Building 527—Motor generator building on pier 2
- Building 530—Auto Hobby Shop
- Building 600—Bachelor Enlisted Quarters, E.M. Barracks
- Building 606—Police Station
- Building 704—Equipment holding shed, Radioactive Material Storage Area, Transportation Shop car shelter
- Building 707—Animal hospital medical building, NRDL annex, Animal colony, waste processing
- Building 708—NRDL Bio-med Facility/animal research, Animal psychology study colony
- Building 709—Navy Exchange Gas Station
- Building 710—Latrine

The Atomic Bomb and Nuclear Research

During World War II, HPS was at times used to load and outfit ships prior to embarkation. On July 15, 1945, the USS *Indianapolis* was docked at Hunters Point awaiting orders. On that date, components of the atomic bomb "Little Boy" were loaded aboard the *Indianapolis* for transport to the South Pacific. It was reported to have contained half of the available uranium in the United States. The ship left Hunters Pont at 6:30 the next morning but was held in San Francisco, awaiting the results of the first atomic weapons test in New Mexico. The test was a success and the *Indianapolis* sailed out of the Golden Gate at 8:30 A.M. and transported the bomb to Tinian in the Marianas Islands. On August 6, 1945, the bomber Enola Gay dropped "Little Boy" on Hiroshima, essentially ending World War II.

Nuclear weapons development was the impetus for the Navy's decision to research protection devices to shield soldiers and civilians from exposure to radioactivity. A nuclear research facility was developed at HPS beginning in 1944 due to its advantageous geographic, political, and logistical attributes. Called the Naval Radiological Defense Laboratory (NRDL), it became a leader in nuclear testing. "NRDL personnel were involved in all atomic weapons tests between 1950 and 1958, providing test support, primarily related to radiation safety and monitoring."[241] After 1951, the NRDL took over many of the buildings on the southern half of the shipyard. The NRDL closed in 1969. Other activities at the Shipyard declined in the 1960s and early 1970s, the Navy officially closed the shipyard in 1974. After 1976, most of the Shipyard was leased to Triple A Machine Shop, a private ship-repair operation. In 1986, the Navy reclaimed the Shipyard for the purposes of environmental remediation with the eventual goal of removing the property from federal ownership (refer to Section III.K [Hazardous Materials] of this EIR for a detailed discussion of the cleanup activities).

Historic Context Themes

Context themes provide a basis for the evaluation of resources and can be arranged either geographically or thematically. The two context themes below, Chinese Fishing Villages and Maritime History, represent important themes in the history of the Hunters Point related to extant resources.

Chinese Fishing Villages

The Chinese fishing villages played an important role in the history of Hunters Point and San Francisco Chinese community. Between the 1870s and the 1900s, Chinese fishing camps flourished in San Francisco and elsewhere around the Bay. Most of the fishing camps were started by workers who were out of work after the completion of the transcontinental railroad in 1869. The Chinese developed the shrimp fishing industry, created largely by the presence of shrimp at their fishing locations and the use of bag nets. Before the late 1860s fishermen caught a variety of fish. By the late 1860s, the Chinese shrimp fishing was a fully developed industry. A substantial amount of dried fish, abalone, abalone shells, and shrimp were exported to China.

[241] Circa Historic Property Development, *Historic Context for the Bayview Waterfront Plan*, p. 114, December 2008.

The amount of San Francisco fish and shrimp exported overseas led fishermen of other ethnicities to petition the State to levy taxes on Chinese commercial fishing. In 1885 and 1886, six hundred Chinese were arrested for tax reasons. The federal government revived old trade-laws and applied them to the dried fish and shrimp trade. Chinese vessels were seized and their captains fined.

The number of Chinese camps around the Bay decreased from 50 in the 1880s to 26 in 1896. The 1900 US Census lists one Chinese fisherman at Hunters Point, but there is no evidence of large-scale fishing camps in the area. The State Legislature outlawed the bag net in 1910, and most of the shrimp fishermen abandoned the industry. A redesign of the bag net, which permitted trolling for shrimp, was introduced in the 1920s. By the 1930s the empty fishing villages were again active. No fewer than twelve fishing camps were observed along Hunters Point shoreline.

In 1939, the San Francisco Health Department, responding to complaints about the pungent smell of the fishing camps, declared the camps unsanitary and ordered several of them burned. The fishing activity declined also because of Bay fill and pollution, and the movement of the Navy to Hunters Point in the 1940s. One camp, the Hunters Point Shrimp Company, closed as late as 1959.

Chinese fishing camps have been recorded at the Project site, primarily at Hunters Point. Although no known Chinese shrimp camps were located in the Candlestick Point area, this does not preclude the possibility that unidentified camps existed within that area. In contrast, fishing camps were widespread in at Hunters Point. Two possible locations for a fishing camp that dates to the 1860s have been identified in HPS.

The presence of Chinese fishing settlements in the Hunters Point area from the late nineteenth century to the mid twentieth century indicates that the Project site is likely to contain potentially significant archaeological resources. The archaeological resources would be the remnant cultural materials that would provide important information regarding the Chinese inhabitants of the Project site and the role of Chinese fishermen in the greater San Francisco Chinese community.

Maritime History

The Project site's shoreline with access to deep water became an early center for maritime activities. Small shipyards, crowded out of the waterfront closer to the City's center, began operating in and adjacent to the Project site as early as the 1860s. By the end of the nineteenth century, the Project site contained shipyards, a drydock, and other related enterprises along the northern shore of Hunters Point. Most of the boats built and repaired at Hunters Point were scow schooners (a boat with a broad, shallow hull instead of a deep keel), and two boatyards adjacent to the Project site in India Basin are known to have built junks (a boat with a flat bottom, no keel, and a very large rudder) for Chinese fishermen.

The drydock facilities at Hunters Point were the largest enterprise within the Project site in the late nineteenth century. The California Dry Dock Company constructed the first drydock in 1867. A second drydock was built in the early 1900s by the San Francisco Dry Dock Company. After the second dock was constructed, Navy ships came to the area for drydock service. In 1908, the Union Iron Works, a division of the Bethlehem Shipbuilding Company, purchased the operation from the San Francisco Dry Dock Company, which later became the Union Iron Works Dry Docks.

Paleontological Setting

The Project site is a rock and soil promontory in southeastern San Francisco extending east into San Francisco Bay. The ground surface in the waterfront area across the entire Project site is relatively flat with elevations ranging from approximately 0 feet to +20 feet San Francisco City Datum (SFCD). Maximum ground surface elevation in the Project vicinity is on Bayview Hill (west of Candlestick Point), approximately +400 feet SFCD. Alluvial, colluvial, and estuarine sediments of the Late Pleistocene and Holocene Epochs (less than one million years old) underlie much of the Project vicinity and were deposited in a structurally controlled basin (San Francisco Bay) as the basin as subsided. These sediments consist of estuarine deposits of older Bay mud, undifferentiated sedimentary deposits (interbedded freshwater and marine sand, clayey sand, and very stiff, lean clay containing shell fragments), younger Bay mud, and alluvial/colluvial deposits (slope debris of clay, sandy clay, sandy silt, sand, silty gravel, etc.), all of which rest on a variety of deformed and metamorphosed bedrock types associated with the Franciscan Complex of the Early Cretaceous Period (between 97 million and 113 million years old in the vicinity of the Project site). Section III.L (Geology and Soils) includes detailed descriptions of the soils and rock units.

Fossils are typically found in river, lake, and bog deposits, although they may occur in nearly any type of sedimentary sequence. The predominant rock types at the Project vicinity are chert, shale, and greenstone in the Candlestick Point area adjacent to the Bay and serpentinite, chert, sandstone, and shale in the HPS Phase II site. Although uncommon in the low-grade metamorphic Franciscan rocks, fossils from widely scattered localities have been important in sorting out the depositional history of the Franciscan Complex. A Cretaceous ammonite was found in Franciscan shale in northeastern San Francisco, as were fossil plant remains (usually reported as carbonaceous matter or carbonaceous particles and layers), and thin shells resembling parts of arthropods. Tiny shark's teeth are the only known vertebrate fossils reported from the Franciscan Complex.

The undifferentiated Late Pleistocene sediments may include deposits of the Colma Formation which contains marine and terrestrial fossils including bones and teeth of mammoth and extinct bison and ground sloth, juniper and red cedar. Holocene pollen, plant, and shell fossils have been reported in the Bay mud. Remains of land mammals (extinct mammoth, bison, and horse) have been reported from localities in younger alluvium along the bay margin south of the Bay Bridge San Francisco Anchorage. No fossils have been reported from artificial fill in the San Francisco Bay area.

Expected Cultural and Paleontological Resources

Prehistoric Resources

Sixteen prehistoric archaeological sites are located in or within a quarter-mile of the Project site. These include CA-SFR-3, CA-SFR-7, CA-SFR-8, CA-SFR-9, CA-SFR-10, CA-SFR-11, CA-SFR-12, CA-SFR-13, CA-SFR-14, CA-SFR-15, CA-SFR-16, CA-SFR-17, CA-SFR-18, CA-SFR-110, CA-SFR-124, and the Thomas-Hawes Mound.

Site CA-SFR-7 (Bayshore Mound, Johnson Landing Mound) has been determined to the eligible for the National Register of Historic Places (NRHP). Excavations performed in 1910 at CA-SFR-7 yielded several human burials. The site was subsequently heavily disturbed and material from the site used to fill a nearby

marsh. Recent auger testing conducted in 2008 indicates that despite the prior disturbance of the site, significant portions of the site still exist underneath fill material. Site CA-SFR-17 was first excavated in 1931 and it also contained several human burials. This site was covered by fill material soon after excavation efforts. The site area was later archaeologically tested in 1987 with auger bores. This testing found that the topmost portion of the site was still intact and was buried 12 to 16 feet below the modern surface. The deposit was in places eight feet thick and extended over an area 650 feet long and 200 feet wide. Site CA-SFR-17 has been determined to be potentially eligible for the NRHP. CA-SFR-110 was located underneath Griffith and Revere Streets. The top portion of the shellmound had been leveled by development, but the remaining deposit was from four to seven feet thick and buried under eight to ten feet of landfill. The site measured approximately 400 feet long and extended halfway between Shafter and Thomas Streets.

One of the sixteen sites, CA-SFR-124, was discovered during monitoring for the Bayview Extension of the Auxiliary Water Supply System in 1990.[242] The site consisted of a shell midden and measured 205 feet long and extended on both sides of Lane Street. The deposit was relatively thin, at most only one foot thick. It was also shallow, on average only six inches below roadbed material. This site may have been re-deposited from another area during historic times. Trench profiles showed the prehistoric deposit overlain old utilities pipes as well as a fill deposit that contained historic-era artifacts. The researchers noted, however, that intact deposits probably were present west of Lane Street.

Since the bedrock is shallow and close to the surface in the Candlestick Point area resources are also expected to be relatively shallow in areas formerly on land. The northern areas of the site are above sea level (+15 feet above San Francisco City Datum), and the historic and recent prehistoric surface has not been significantly altered. In the early twentieth century, Nels C. Nelson found and excavated prehistoric site CA-SFR-9 at Candlestick Point in the area that is now the stadium; however, the extent of the excavation is unknown. The southern area of the site, which was submerged beneath Bay waters during the historic era, is covered with fill. Before filling, the Bay in this area was relatively shallow, less than 10 feet below sea level. Thus, the highest potential for intact cultural deposits is below the fill and above the original Bay floor. It is also possible that prehistoric resources may have been removed from their original location and may be found within fill deposits in the southern (southeastern) area of the site.

The waters of the San Francisco Bay originally covered all but the northernmost portion of HPS during the later nineteenth and early twentieth centuries. In the northern upland portion of the Shipyard, the bedrock is shallow and is close to the surface. Before filling, the Bay floor was much shallower in the northern portion (near the original Hunters Point peninsula) than in the southern portion. In areas originally underwater, the area of the highest sensitivity ranges from about 20 feet (closer to northern portion) to about 60 feet (southern portion) below present ground surface.

- Based on archival research, the following indigenous sites are known or are believed to be located within the boundaries of the Project site. Some sites have not been evaluated for eligibility for listing on the California Register of Historic Resources (CRHR) or National Register of Historic Places, since most are

[242] Holman & Associates, *Report on Archaeological Monitoring of the Bayview Extension of the Auxiliary Water Supply System and Observations on CA-SFR-124, a Shell Midden Deposit at Lane Street and Shafter Avenue, Bayview District, San Francisco, California*, Rohnert Park, CA: Northwest Information Center, 1991.

under fill or on areas that have been developed. However, if a site or portion of a site contains intact archaeological deposits it would be considered a significant archaeological resource.[243]

- **CA-SFR-7**

Site CA-SFR-7, as described above, has been determined to the eligible for the National Register of Historic Places (NRHP). The site is at the western end of Candlestick Point.

CA-SFR-9

Site CA-SFR-9 has been identified with Nelson's Site #389.[244] The site record provides no description, but suggests it was probably a shell midden. The San Francisco Major Environmental Analysis (MEA) Shellmound Data Base indicates that it was located at the east end of Candlestick Point approximately 0.375 mile northeast of CA-SFR-7.[245]

CA-SFR-12

Site CA-SFR-12 is a shellmound, recorded by Nelson as Site #391 on the south side of Hunters Point.
- More recently, Hamusek-McGann et al. used an archaeological predictive model to identify the likely location of the site in HPS.[246]

CA-SFR-13

Recorded by Nelson as Site #392, site CA-SFR-13 may be located at the eastern end of Hunters Point.[247]
- More recently, Hamusek-McGann et al. used an archaeological predictive model to identify the likely location of the site in HPS.[248] Hamusek-McGann et al. report that based on historical maps the probable location of this site would have placed it at the original shoreline where Drydock 4 was later built. Due to extensive excavations that occurred during construction of the drydock Hamusek-McGann et al. assume that CA-SFR-13 was destroyed; however, as with other sites that were later determined to be wholly or partially intact, such as CA-SFR-7, CA-SFR-17, and CA-SFR-140, this site might also present intact discoveries.

CA-SFR-14

Site CA-SFR-14 is probably a mound, recorded by Nelson as Site #392a on the northeast end of Hunters
- Point. More recently, Hamusek-McGann et al. used an archaeological predictive model to identify the likely location of the site in HPS.[249]

---

[243] An intact archaeological deposit is one in which the original or stratified association of archaeological remains are retained within an archaeological site.

[249] Hamusek-McGann, B., Baker, C., & Maniery, M. 1998.

CA-SFR-11

Site CA-SFR-11 is a shell midden recorded as Nelson's Site #390 on the south side of Hunters Point.[250] More recently, Hamusek-McGann et al. used an archaeological predictive model to identify the likely location of the site inside HPS.[251]

However, the MEA Shellmound Archaeo GIS Project map also places the site at another location—one immediately northeast of the Project boundary.[252] This appears to support Olmsted's original observation that the site Nelson designated as Mound #390 was situated on Palou Avenue near the shoreline.[253] The site appears to be in the western part of Hunters Point Shipyard Phase II.

Chinese Fishing Village Sites

The remains of many Chinese fishing camps may still exist within the Project site. Camps and villages at HPS date from 1853 up to the 1940s. Documents show that at least four camps containing a total of 206 fishermen existed in the 1860s; 2000 fishermen were on the Project site in the 1880s. Records are scant for the period between 1890s and 1910. This reflects a decrease in fishing. By 1910, the fishing industry returned, and five companies were known to exist. The 1920s saw a decrease to possibly three camps on the Project site. By the 1930s, the number of camps in the Project site attained its highest level, with at least 12 camps documented.

Camp locations would have included a range of domestic and work-related structures associated with the shrimp industry. Most camps followed a similar layout, although this would have changed over time as population, technology, and social conditions changed. Typically a camp consisted of several small shacks at the water's edge, a wharf, a processing area with boilers, drying grounds, storehouses, and living quarters. Since Chinese fishing camps were located near the Bay, the original shoreline and adjacent beach should be considered highly sensitive for these types of resources. Chinese fishing village sites at the Project site that contain intact archaeological deposits would be considered significant archaeological resources.

Maritime Sites

A variety of maritime-related resources are the most likely potential historic archaeological resources within the Project site, including boatbuilding and small craft repair facilities; large ship repair and drydock facilities; buried ships; and maritime-related waterfront infrastructure. Boatbuilding resources may include tools used to build and repair the ship; remnants of wood, metal, textiles, and rope used to build the ship; and discarded items related to the ship carpenter, ship laborers, and apprentices.

The California Dry Dock Company, later the San Francisco Dry Dock Company, operated a drydock facility at the tip of Hunters Point. Boarding houses built near the drydocks were frequented by sailors and passengers. It is possible that refuse from the drydock operations, its employees, ship crew, and passengers may exist beneath the modern fill. Drydock resources may include the dock, hardware related to the

construction of the dock, personal items, and refuse associated with boarding houses that were frequented by sailors and passengers while the ship was at dock.

Buried ship resources may include shipwrecks, abandoned hulks, and ships that were converted into residences during the 1930s. Numerous ships have been found buried in San Francisco, most of which were buried as the city's shoreline was extended during land filling operations. A search of the California State Lands Commission's online shipwreck database revealed six ships that wrecked in or in close proximity to Hunters Point. Fragments of these wrecks and their cargo may have washed ashore or used as landfill and may be buried within the Project site as the shoreline was filled in. Few shipwrecks that date to the nineteenth century have been archaeologically studied and documented. Most of the studies have involved only the portion of the wreck that was encountered or the bottom of the hulls. Documentation of complete vessels is extremely rare. Although these deposits may not be complete specimens or in their original location, remains of shipwrecks, abandoned hulks, and ship cargo may be able to answer important research questions relating to maritime trade, ship wrecks, abandonment, or reuse of the wreck.[254]

Waterfront infrastructure resources may include wharves, retaining walls, driven piles, ship-breaking yards, and hardware related to the construction of these resources.

Any sites that contain onshore or offshore maritime archaeological deposits that have the potential to adequately address research questions such as those presented in the Archaeological Research Design and Treatment Plan for the Project[255] would be considered significant archaeological resources.

Historic Resources

Candlestick Point

The Candlestick Point site does not contain historic resources. In 2007, Jones & Stokes completed a review of Candlestick Park stadium, built in 1960, for potential eligibility in the NRHP.[256] The evaluation determined that the stadium did not meet the criteria to qualify as an exceptional property less than 50 years old. The report noted extensive alterations since its construction, including the expansion and enclosure in 1970 and more recent modifications to convert the stadium into a football-only facility. A recent Historic Resource Evaluation (HRE) reviewed the stadium as a 50-year-old structure and the HRE concluded that, while the stadium would meet certain NRHP and CRHR criteria for association with events and persons, specifically the expansion of Major League Baseball to the West Coast and the career of Willie Mays with the San Francisco Giants, the stadium does not retain sufficient integrity to qualify as an historic resource under NRHP or CRHR criteria.[257] The Alice Griffith public housing site was evaluated as part of this EIR and determined ineligible for listing on the NRHP, CRHR, or City landmark registers because it was not strongly associated with a significant historical event, was not directly associated with Alice Griffith's productive life, is not distinctive architecturally, and does not have the potential to yield additional important historical information. No other potential historic resources have been identified in the Candlestick Point area.

Hunters Point Shipyard

The HPS Phase II site contains buildings and structures identified historic significance. Since Shipyard decommissioning in 1974, two studies evaluated historic resource at the Shipyard. In 1988, a report concluded that four properties were eligible for listing on the NRHP: Drydock 4; Building 253; the 450-ton Re-gunning crane, and the Hunters Point Commercial Dry Dock Historic District (including Drydock 2, Drydock 3, remnants of Drydock 1 and Buildings 140, 204, 205, and 207).[258] The Deputy State Historic Preservation Officer (SHPO) concurred with the findings of the 1988 report. In 1997, JRP Historical Consulting Services completed an updated report for HPS and concluded that Drydock 4 and the potential Hunters Point Commercial Dry Dock Historic District appeared eligible for listing in the NRHP. The JRP report concluded that Building 253 and the Re-gunning crane, identified in the 1988 study, were not eligible due to integrity issues. In 1998, the SHPO concurred with findings that the Drydock 4 and the potential Hunters Point Commercial Dry Dock Historic District appeared eligible for inclusion in the NRHP.[259] The Navy is currently completing National Register nominations and Historic American Engineering Records documentation for the Hunters Point Commercial Dry Dock Historic District, pursuant to the Memorandum of Agreement with SHPO and the Advisory Council on Historic Preservation, discussed under "Regulatory Framework," below.

- The Office of Historic Preservation Directory of Properties in the Historic Property Data File included Drydocks 2 and 3 pump houses (Buildings 205 and 140), the western portion of Drydock 1, the Gatehouse (Building 204), and the Paint and Tool Building (Building 207) as the only structures on HPS considered eligible for listing on the NRHP, consistent with the findings of the 1997 JRP report and the subsequent SHPO concurrence. No other buildings or structures had previously been evaluated for listing on the CRHR.

- In 2008, Circa Historic Property Development performed another investigation of HPS for this EIR. Circa identified a total of 134 buildings and structures at the HPS Phase II site. The investigation evaluated the eligibility of buildings and structures for the NRHP, the CRHR, or local historic registers. Since Circa's initial investigation four of these buildings have been demolished including Buildings 365, 408, 421, and 916. Of the 130 remaining buildings and structures, 11 were identified as part of a CRHR-eligible historic district the potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District. This district includes buildings, structures, and objects associated with the area's "transition from early commercial drydock operation to high tech naval repair and Radiological research."[260] The proposed expanded historic district is potentially eligible for the CRHR, though it encompasses NRHP eligible properties. The Period of Significance has been identified as 1901–1963. Contributing resources in the district include the first six structures listed below which were initially identified as part of the NRHP eligible Hunters Point Commercial Dry Dock Historic District in 1998, and the five additional structures identified by Circa in 2008. Figure III.J-2 (Potential Historic District) shows the location of the potential historic district:

As noted earlier, Drydock 4, located in the HPS Phase II site, is additionally eligible for individual listing on the NRHP.

Potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District

According to the California Office of Historic Preservation, historic districts "consist of a significant concentration or continuity of associated historical resources. [They] may be recognized and documented at the time a survey is conducted, or they may become apparent only after several survey efforts reveal the historical relationships among the individually recorded resources in a given geographic region." National Register Bulletin No. 15, How to Apply the National Register Criteria for Evaluation, states that, "A district derives its importance from being a unified entity, even though it is often composed of a wide variety of resources. The identity of a district results from the interrelationship of its resources, which can convey a visual sense of the overall historic environment or be an arrangement of historically or functionally related properties."

HPS has a long history that began during a period of transition between wood-hulled sailing vessels and steel-hulled motor-driven vessels and ended with modern military craft. It serviced private ships during the height of shipping on San Francisco Bay as well as military ships during four major wars/conflicts (Spanish-American War, World War I, World War II, and the Korean Conflict). Towards the end of this period, it also served as a major radiological research facility that was unique within the United States military. This evaluation includes buildings that individually represent these various areas of significance and collectively demonstrate the broad spectrum of historical development at the Shipyard.

The potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District is comprised of a collection of buildings, structures, and objects associated with the area's transition from early commercial drydock operation through its period of radiological research. The district encompasses a range of buildings from each of the three primary periods of significance for HPS: early drydocks, Navy use in World War II, and radiological research in the World War II and post-war periods. Related site features associated with the district include light standards, rail spurs, crane tracks, drydock perimeter fencing, bollards, and cleats.

The potential historic district encompasses a cross section of buildings, structures and objects, varying in age and function from the early commercial drydock operations (1903), through the Shipyard's function as a high tech naval ship repair and decontamination facility in World War II, and as a ship repair and radiological research facility in the post-war period (1946–1969). The industrial buildings (140, 204, 205, 207, 208, 211, 231, 224, and 253), Drydocks 2 and 3, and other related site features represent a microcosm of the historical development and context of HPS. The potential district contains previously determined National Register eligible buildings (automatically listed as a district on the CRHR) as well as recommended contributors to an expanded, potential CRHR Historic District (including Drydock 2, Drydock 3, and Buildings 140, 204, 205, 207, 208, 211, 224, 231, and 253). The proposed contributors to the expanded CRHR eligible district include the previously eligible NRHP district contributors plus Buildings 208, 211, 224, 231, and 253. Though the condition of the buildings ranges from good to fair, the potential district as a whole retains a high degree of integrity of location, design, setting, workmanship, materials, association, and feeling.

A district can comprise both features that lack individual distinction and individually distinctive features that serve as focal points. While Buildings 208, 211, 224, 231, and 253 may not be individually eligible for listing on the CRHR, when combined with the historic drydocks and associated buildings, the district is a physical representation of the broad history of HPS. Figure III.J-3 (Potential Historic Structures) illustrates views of Buildings 211, 224, 231, and 253.

Candlestick Point — Hunters Point Shipyard Phase II EIR

POTENTIAL HISTORIC STRUCTURES

FIGURE III.J-3

No buildings remain from the earliest drydock operations within the historic district boundaries. Remnants of Drydock 1 (1868) may or may not exist in the area with sufficient potential to yield information that make the property eligible for the NRHP. Until existence of the remnants of Drydock 1 has been demonstrated, its location should be treated as an archaeologically sensitive area and as a potential contributing element of the district. Refer to the "Archaeological Resources" section below for a discussion of maritime archaeological resources.

Paleontological Resources

Fossils have been reported in Franciscan rocks.[261] Radiolarian chert beds in the Franciscan Complex contain microfossils of radiolarian—the silicon-based skeletons of single-celled planktonic marine organisms—which are important as stratigraphic markers. Limestone nodules and concretions in Franciscan shales, and the shales themselves, often contain radiolaria, foraminifera (another single-celled marine organism), gastropods (snails), pelecypods (clams), and plant microfossils (pollen and spores). Exposures of Franciscan rocks in the vicinity of the Project appear non-fossiliferous.[262] The undifferentiated Pleistocene sediments, which may encompass some of the Colma Formation, contain marine and terrestrial fossils including the bones and teeth of mammoth and extinct bison, a leg bone of a ground sloth, and fossil diatoms (single-celled freshwater and marine algae), pollen, and peat.[263] Fossil mollusk shell fragments were recovered from these sediments at a depth of about 30 feet in a geotechnical borehole near Islais Creek, about 1.5 miles along the shore northwest of the Project site. Late Pleistocene and Holocene fossils have been recovered from marine sediments (older Bay mud) near the Bay Bridge San Francisco Anchorage, including remains of petrified wood, marine mollusks and mammals, bony fishes, amphibians, reptiles, birds, a diversity of extinct land mammals such as ground sloths, mammoth, mastodon, deer, horse, camel, and bison, and microfossils such as radiolaria, foraminifera, diatoms, pollen, and spores. Fossil mollusk shells were reported in cores of Holocene younger Bay mud from depths of approximately 20 and 25 feet in the borehole near Islais Creek.[264] No fossils have been reported from artificial fill in the San Francisco Bay area; however, because artificial fill includes sediments from older formations, it is possible that such fossils exist, although fossils transported from their original locations would lack stratigraphic context and be of limited value.[265]

III.J.3 Regulatory Framework

Federal

Federal regulations for cultural resources are primarily governed by Section 106 of the *National Historic Preservation Act of 1966* (NHPA), which applies to actions taken by federal agencies, including projects that take place on federally controlled land or facilities, require federal agency permits, or receive federal funding. The criteria for determining NRHP eligibility are found in 36 *Code of Federal Regulations* (CFR) Part 60. Section 106 of the NHPA requires federal agencies to take into account the effects of their undertakings on historic properties and affords the federal Advisory Council on Historic Preservation a reasonable opportunity to comment on such undertakings. Section 301(7) of the NHPA defines an undertaking as any project, activity, or program funded in whole or in part under the direct or indirect jurisdiction of a federal agency, including:

- Those carried out by or on behalf of the agency
- Those carried out with federal financial assistance
- Those requiring a federal permit, license, or approval
- Those subject to state or local regulation administered pursuant to a delegation of approval by a federal agency[266]

The NHPA also authorizes the Secretary of the Interior to maintain a National Register of Historic Places and directs the Secretary to approve state historic preservation programs that provide for a State Historic Preservation Officer.

The Council's implementing regulations, "Protection of Historic Properties," are found in 36 CFR Part 800. The NRHP criteria (contained in 36 CFR 60.4) are used to evaluate resources when complying with NHPA Section 106. Those criteria state that eligible resources comprise districts, sites, buildings, structures, and objects that possess integrity of location, design, setting, materials, workmanship, feeling, and association, and any of the following:

a) Are associated with events that have made a significant contribution to the broad patterns of our history
b) Are associated with the lives of persons significant in our past
c) Embody the distinctive characteristics of a type, period, or method of construction, or that possess high artistic values, or that represent a significant distinguishable entity whose components may lack individual distinction
d) Have yielded or may be likely to yield, information important to history or prehistory

Archaeological site evaluation assesses the potential of each site to meet one or more of the criteria for NRHP eligibility based upon visual surface and subsurface evidence (if available) at each site location, information gathered during the literature and records searches, and the researcher's knowledge of and familiarity with the historic or prehistoric context associated with each site.

[266] 16 USC 470w(7).

Memorandum of Agreement

In 1999 the Navy entered into a Memorandum of Agreement with the Advisory Council on Historic Preservation and the SHPO regarding the interim lease and disposal and protection of historic properties (Drydock 4 and the Commercial Drydock Historic District) at HPS.[267] Under the MOA the Navy evaluated all building and structures on the Shipyard in consultation with the SHPO, agreed to prepare Registration Forms for the Hunters Point Commercial Drydock Historic and Drydock 2, completed an Archeological Inventory and Assessment, coordinated the disposal of the remaining Shipyard documents, and agreed on the terms of abandonment for Drydock 4. The MOA also laid out the reporting, resolution of objections, and amendment processes for the term of the MOA.

Programmatic Agreement

In 2006/07 a Programmatic Agreement (PA) was signed by the City, the California State Historic Preservation Officer, and the Advisory Council on Historic Preservation. The PA specifically addressed historic properties affected by use of revenue from the Department of Housing and Urban Development Part 58 Programs.

State

Public Resources Code (PRC) Section 5020.5 directs the State Historical Resources Commission to develop criteria and methods for determining the significance of archaeological sites. PRC Section 5024.1 establishes the California Register of Historical Resources and criteria for inclusion of resources on the Register. Under CEQA, public agencies must consider the effects of their actions on both "historical resources" and "unique archaeological resources."

"Historical resource" is a term with a defined statutory meaning (refer to PRC Section 21084.1 and CEQA Guidelines Section 15064.5(a) and (b)). The term embraces any resource listed in or determined to be eligible for listing in the CRHR. The CRHR includes resources listed in or formally determined eligible for listing in the NRHP, as well as some California State Landmarks and Points of Historical Interest. In addition, properties of local significance that have been designated under a local preservation ordinance (local landmarks or landmark districts) or that have been identified in a local historical resources inventory may be eligible for listing in the CRHR and are presumed to be "historical resources" for purposes of CEQA unless a preponderance of evidence indicates otherwise (PRC Section 5024.1 and *California Code of Regulations* (CCR), Title 14, Section 4850). Unless a resource listed in a survey has been demolished, lost substantial integrity, or there is a preponderance of evidence indicating that it is otherwise not eligible for listing, a lead agency should consider the resource to be potentially eligible for the CRHR and as a historical resource under CEQA.

In addition to assessing whether historical resources potentially impacted by a proposed project are listed or have been identified in a survey process, lead agencies have a responsibility to evaluate them against the CRHR criteria prior to making a finding as to a proposed project's impacts to historical resources (PRC Section 21084.1 and CEQA Guidelines Section 15064.5(a)(3)). In general, an historical resource, under this approach, is defined as any object, building, structure, site, area, place, record, or manuscript that:

[267] *Hunters Point Shipyard Reuse Final Environmental Impact Report, Volume 1*, page 3-159, February 2000.

(a) Is historically or archeologically significant, or is significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political or cultural annals of California; and

(b) Meets any of the following criteria:

1) Is associated with events that have made a significant contribution to the broad patterns of California's history and cultural heritage;

2) Is associated with the lives of persons important in our past;

3) Embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of an important creative individual, or possesses high artistic values; or

4) Has yielded, or may be likely to yield, information important in prehistory or history.

(CEQA Guidelines Section 15064.5(a)(3))

Under CEQA, the significance of an historical resource is materially impaired when a project "demolishes or materially alters in an adverse manner those physical characteristics of an historical resource that convey its historical significance" (CEQA Guidelines Section 15064.5(b)(2)(A) and that justify or account for its inclusion in, or eligibility for inclusion in, the CRHR. Thus, a project may cause a substantial change in an historical resource but still not have a significant adverse effect on the environment as defined by CEQA, so long as the historical resource continues to convey its historical significance.

CEQA Guidelines Section 15064.5(b)(3) states that "generally, a project that follows the Secretary of the Interior's Standards for the Treatment of Historic Properties with Guidelines for Preserving, Rehabilitating, Restoring, and Reconstructing Historic Buildings or the Secretary of the Interior's Standards for Rehabilitation and Guidelines for Rehabilitating Historic Buildings shall be considered as mitigated to a level of less than a significant impact on the historical resource."

CEQA requires that the effects of a project on an archaeological resource shall be taken into consideration and that if a project may affect an archaeological resource that it shall first be determined if the archaeological resource is an "historical resource", that is, if the archaeological resource meets the criteria for listing in the California Register of Historical Resources (CRHR). To be eligible for listing to the CRHR under Criterion 1, 2, or 3, an archaeological site must contain artifact assemblages, features, or stratigraphic relationships associated with important events, or important persons, or exemplary of a type, period, or method of construction (CEQA Guidelines Section 15064.5(a)(1) and (3) and (c)(1) and (2)). To be eligible under Criterion 4, an archaeological site need only show the *potential* to yield important information. An archaeological resource that qualifies as a "historical resource" under CEQA, generally, qualifies for listing under Criterion 4 of the CRHR (CEQA Guidelines Section 15064.5(a)(3)(D). An archaeological resource may qualify for listing under Criterion 4 when it can be demonstrated that the resource has the potential to significantly contribute to questions of scientific/historical importance (CA OHP. *Preservation Planning Bulletin* No. 5).

CEQA Guidelines Section 15064.5(e) requires that excavation activities be stopped whenever human remains are uncovered and that the county coroner be called in to assess the remains. If the county coroner determines that the remains are those of Native Americans, the Native American Heritage Commission (NAHC) must be contacted within 24 hours. At that time, the lead agency must consult with the appropriate Native Americans, if any, as timely identified by the NAHC. Section 15064.5 directs the lead agency (or applicant), under certain circumstances, to develop an agreement with the Native Americans for the treatment and disposition of the remains.

Local

San Francisco General Plan and Planning Department Procedures

General Plan

The Urban Design Element of the City of San Francisco *General Plan* acknowledges the importance of historic structures within the City, and emphasizes the importance of older buildings for the "richness of character, texture, and human scale that is unlikely to be repeated often in new development." These structures help to characterize many neighborhoods and serve as landmarks and focal points. General Plan policies regarding architectural resources are discussed in Objective 2 of the Urban Design Element:

Objective 2 Conservation of resources which provide a sense of nature, continuity with the past, and freedom from overcrowding.

- Policy 2.4 Preserve notable landmarks and areas of historic, architectural, or aesthetic value, and promote the preservation of other buildings and features that provide continuity with past development.
- Policy 2.5 Use care in remodeling of older buildings, in order to enhance rather than weaken the original character of such buildings.
- Policy 2.6 Respect the character of older development nearby in the design of new buildings.

The Bayview Hunters Point Area Plan

The *Bayview Hunters Point Area Plan* of the *San Francisco General Plan* was adopted by the Planning Commission in March 2006 to guide the future development of the Bayview Hunters Point district of San Francisco. One goal of the *Bayview Hunters Point Area Plan* is to conserve the archaeological and cultural heritage of Bayview's indigenous population.

The *Bayview Hunters Point Area Plan* recognizes the significance of this deep cultural heritage, and accordingly views the entire geographical area covered by the Plan as having potential archaeological significance. Under this view, archaeological investigation and plan remediation are encouraged for any substantial proposed physical development with the potential to encounter buried archaeological resources within the boundaries of Bayview.[268]

City and County of San Francisco Planning Department CEQA Review Procedures for Historic Resources

The San Francisco Planning Department considers a listing of historical resources approved by ordinance or resolution of the Board of Supervisors or the Planning Commission to be a local register of historical resources for the purposes of CEQA evaluation.[269] San Francisco Preservation Bulletin No. 16 provides guidance for the CEQA review process with regard to historic resources. As a certified local government and the lead agency in CEQA determinations, the City has instituted guidelines and a system for initiating

[268] Articles 10 and 11 are in the process of being revised to account for changes that have resulted from the approval of the HPC.

[269] *Public Resources Code* Sec. 5020.1(k) states, "'Local register of historical resources' means a list of properties officially designated or recognized as historically significant by a local government pursuant to a local ordinance or resolution."

CEQA review of historic resources. The San Francisco Planning Department's "CEQA Review Procedures for Historical Resources" incorporates the CEQA Guidelines into the City's existing regulatory framework. To facilitate the review process, the Planning Department has established the categories to determine the baseline significance of historic properties based on their inclusion within cultural resource surveys and/or historic districts. These categories include Category A.1 (Resources listed on or formally determined to be eligible for the CRHR), Category A.2 (Adopted local registers, and properties that have been determined to appear or may become eligible, for the CRHR), Category B (Properties requiring further consultation and review), Category C (Properties determined not to be historical resources or properties for which the City has no information indicating that the property is an Historical Resource).

Paleontological Resources

A variety of federal, state, and local regulations and policies protect paleontological resources. These include, NEPA, CEQA, the federal Antiquities Act of 1906, the National Natural Landmarks Program, and the PRC. Under California law, paleontological resources are included in CEQA[270] and are required to be examined as part of the CEQA process. The City has no policies directly protecting paleontological resources, but uses the CEQA process to address potential adverse effects.

CEQA requires that paleontological resources be addressed during the EIR process. CEQA Guidelines, Appendix G, states, in part, that a project will "normally" have a significant effect on the environment if, among other things, it will disrupt or adversely affect a paleontological site, except as part of a scientific study. If paleontological resources are identified during the initial project scoping studies (such as an Initial Study or in a comment on the Notice of Preparation) as being on the project site, the Lead Agency must take those resources into consideration when evaluating the potential effects of the project. In the context of the PRC (Section 5097.5), fossils of vertebrates and evidence of their environment generally are considered important (i.e., "significant") paleontological resources.

III.J.4 Impacts

Significance Criteria

The CCSF and Agency have not formally adopted significance standards for impacts related to cultural or paleontological resources, but generally consider that implementation of the proposed Project would have significant impacts on these resources if it were to:

- J.a Cause a substantial adverse change in the significance of a historical resource as defined in CEQA Guidelines Section 15064.5, including those resources listed in Article 10 or Article 11 of the *San Francisco Planning Code*
- J.b Cause a substantial adverse change in the significance of an archaeological resource pursuant to CEQA Guidelines Section 15064.5
- J.c Disturb any human remains, including those interred outside of formal cemeteries
- J.d Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature as defined in CEQA Guidelines Section 15064.5 (3)

[270] *California Administrative Code*, Title 14, Section 4306 et seq., and *Public Resources Code* Section 5097.5.

Analytic Method

The impact analysis for cultural resources is based primarily on the information contained in the following reports, *Historical Context for the Archaeology of the Bayview Waterfront Project, San Francisco, California*, July 2008; *Archaeological Research Design and Treatment Plan for the Bayview Waterfront Project, San Francisco, California*, June 2009; *Historic Context for the Bayview Waterfront Plan*, December 2008, and the *Bayview Waterfront Plan Historic Resources Evaluation, Volume II: Draft Historic Resources Survey and Technical Report*, July 2009. The technical studies incorporate archival research, site reconnaissance, and interviews with public agency staff and other informed contacts.

The paleontological resource impact analysis is based on databases searches of the University of California Museum of Paleontology; the American Museum of Natural History, Division of Paleontology; the North American Mammalian Paleofaunal Database in July 2009; and a review of published studies by the United States Geological Survey and other agencies and organizations to identify previously reported fossil finds in the vicinity of the Project site or in the same geologic units that occur at the Project site.

Additionally, the Project's potential contribution to cumulative cultural resource impacts are evaluated in the context of existing, proposed, and reasonably foreseeable future development expected in the Project vicinity. The cumulative context for each type of resource is unique and described in the cumulative impacts section below.

Construction Impacts

Impact CP-1a: Change in Significance of Historical Architectural Resources

Impact of Candlestick Point

Impact CP-1a **Construction at Candlestick Point would not result in a substantial adverse change in the significance of an historical resource. (Less than Significant)** ***[Criterion J.a]***

The Project would demolish Candlestick Park stadium, and would demolish and redevelop the Alice Griffith public housing site. Neither Candlestick Park stadium, nor the Alice Griffith public housing sites are considered eligible for listing on the NRHP, CRHR, or City landmark registers. As discussed above, while the stadium would meet certain NRHP and CRHR criteria for association with events and persons, the stadium does not retain sufficient integrity to qualify as a historic resource. At the time the stadium was analyzed, it was less than 50 years old; however, if reviewed at the 50-year mark, it still would not meet criteria for listing on the NRHP or CRHR due to lack of physical integrity resulting from the extensive alterations discussed above. The Alice Griffith public housing site was determined ineligible for listing on the NRHP, CRHR, or City landmark registers because it was not strongly associated with a significant historical event, was not directly associated with Alice Griffith's productive life, is not distinctive architecturally, and does not have the potential to yield additional important historical information. No other potential historic resources have been identified in the Candlestick Point area of the Project site. Therefore, the Project's construction effects on historic resources at Candlestick Point would be less than significant. No mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact CP-1b **Construction at HPS Phase II could result in a substantial adverse change in the significance of an historical resource. (Significant and Unavoidable with Mitigation) *[Criterion J.a]***

Historical resources at HPS Phase II include the potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District, with buildings, structures, and objects associated with the area's "transition from early commercial drydock operation to high-tech naval repair and Radiological research and waste treatment facility."[271] Contributing resources in the potential Hunters Point Historic District include Drydock 2, Drydock 3, and Buildings 140, 204, 205, 207, 208, 211, 224, 231, and 253.

The Project proposes to retain the buildings and structures in the potential Hunters Point Commercial Dry Dock District, identified in 1998 as eligible for listing in the NRHP. Drydocks 2 and 3 and Buildings 140, 204, 205, and 207 would be rehabilitated using the Secretary of the Interior Standards for Rehabilitation and Guidelines for Rehabilitating Historic Buildings. Page & Turnbull, architects and historic resource consultants, reviewed the proposed treatment and rehabilitation of Drydocks 2, 3, and 4. The treatments would include repair of concrete surfaces of the drydocks and addition of guardrails along their perimeter. Page & Turnbull found that the proposed treatments would provide a methodology for resolving severe deterioration issues, and ultimately provide for the longevity of the historic resources; the treatments would be consistent with the *Secretary of the Interior's Standards for Rehabilitation*[272] (refer to Appendix J [Drydock Assessment]). Heritage Park is proposed at Drydocks 2 and 3 and would include interpretive display elements related to the history of HPS. Per CEQA Guidelines Section 15064.5(b)(3), these impacts would be mitigated to a less-than-significant level.

- Development at HPS Phase II would result in the demolition of Buildings 211, 224, 231, and 253, which have been determined eligible for the CRHR and are contributors to the potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District. This would be a potentially significant impact because the proposed actions would demolish buildings that contribute to a historic district; the impact would materially alter in an adverse manner those physical characteristics of an historical resource that convey its historical significance and that justify its eligibility for inclusion in the CRHR. None of the buildings proposed for demolition has been determined eligible for individual listing on any register; therefore, the loss of these buildings is evaluated based on the impact to the potential Historic District. The potential Historic District includes two docks and nine buildings; therefore, the Project would demolish nearly 50 percent of the contributing resources and could cause the District to be ineligible for inclusion in the CRHR. Implementation of mitigation measures MM CP-1b.1 and MM CP-1b.2 would reduce those impacts; however, the demolition of historic resources would be a significant impact that cannot be reduced to a less-than-significant level. Therefore, the Project would have a significant and unavoidable impact on the potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District, because of demolition of Buildings 211, 224, 231, and 253. Chapter VI (Alternatives) analyzes

[271] Circa Historic Property Development, *Hunters Point Commercial Dry Dock and Naval Shipyard Historic District DPR form*, October 31, 2008.
[272] Page & Turnbull, Memorandum Regarding Secretary's Standards Evaluation of Proposed Treatments for Dry Docks, October 5, 2009. The memorandum and evaluation was undertaken by professionals who meet the Secretary of the Interior's Professional Qualification Standards in Historic Architecture and Architectural History.

Alternative 4 (Reduced CP-HPS Phase II Development; Historic Preservation; State Parks Agreement; No HPS Phase II Stadium, Marina, or Yosemite Slough Bridge). Alternative 4 would include rehabilitation and reuse of Buildings 211, 224, 231, and 253 in the potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District. Building 208 would be mothballed and maintained as an element of the cultural landscape. Chapter VI also contains an analysis of Subalternative 4A (CP-HPS Phase II Development Plan with Historic Preservation), which would additionally include rehabilitation and/or reuse of Buildings 211, 224, 231, and 253, while keeping all other components of the Project the same.

To reduce the impact on historic resources at HPS Phase II, the following mitigation measures shall be implemented:

MM CP-1b.1 *Mitigation to Minimize Impacts on Historic Resources at HPS Phase II. To reduce the adverse effect on historical resources, prior to any structural demolition and removal activities, the Project Applicant shall retain a professional who meets the Secretary of the of the Interior's Professional Qualifications Standards for Architectural History to prepare written and photographic documentation of the potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District, as identified in the report titled* Bayview Waterfront Plan Historic Resources Evaluation, Volume II: Draft Historic Resources Survey and Technical Report*, July 2009, prepared by Circa Historic Property Development.*

The documentation for the property shall be prepared based on the National Park Services' (NPS) Historic American Building Survey (HABS) / Historic American Engineering Record (HAER) Historical Report Guidelines. This type of documentation is based on a combination of both HABS/HAER standards (Levels II and III) and NPS new policy for NR-NHL photographic documentation as outlined in the National Register of Historic Places and National Historic Landmarks Survey Photo Policy Expansion (March 2005).

The written historical data for this documentation shall follow HABS / HAER Level I standards. The written data shall be accompanied by a sketch plan of the property. Efforts should also be made to locate original construction drawings or plans of the property during the period of significance. If located, these drawings should be photographed, reproduced, and included in the dataset. If construction drawings or plans cannot be located as-built drawings shall be produced.

Either HABS / HAER standard large format or digital photography shall be used. If digital photography is used, the ink and paper combinations for printing photographs must be in compliance with NR-NHL photo expansion policy and have a permanency rating of approximately 115 years. Digital photographs will be taken as uncompressed. TIF file format. The size of each image will be 1600x1200 pixels at 300 ppi (pixels per inch) or larger, color format, and printed in black and white. The file name for each electronic image shall correspond with the index of photographs and photograph label.

Photograph views for the dataset shall include (a) *contextual views;* (b) *views of each side of each building and interior views, where possible;* (c) *oblique views of buildings; and* (d) *detail views of character-defining features, including features on the interiors of some buildings. All views shall be referenced on a photographic key. This photograph key shall be on a map of the property and shall show the photograph number with an arrow indicate the direction of the view. Historic photographs shall also be collected, reproduced, and included in the dataset.*

All written and photographic documentation of the potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District shall be approved by the potential SFRA, in consultation with the ERO, prior to any demolition and removal activities.

MM CP-1b.2 *Interpretive Displays Depicting History of HPS. Interpretive displays related to the history of HPS shall be installed at Heritage Park at Drydocks 2 and 3. The number and type of displays shall be approved by the SFRA, in consultation with the ERO.*

These measures would reduce the significant adverse impact of HPS Phase II on the Hunters Point Commercial Dry Dock and Naval Shipyard Historic District, but not to a less-than-significant level.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact CP-1 **Construction activities associated with the Project could result in a substantial adverse change in the significance of a historical resource. (Significant and Unavoidable with Mitigation) *[Criterion J.a]***

Refer to discussions of Impact CP-1a and Impact CP-1b and associated discussions, above. As discussed above, potential impacts to Drydocks 2 and 3 and Buildings 140, 204, 205, and 207 would be reduced to a less-than-significant level by retaining the drydocks and by rehabilitating the buildings, in accordance with the Secretary of the Interior Standards for Rehabilitation and Guidelines for Rehabilitating Historic Buildings.

- As discussed above, the Project would result in the demolition of Buildings 211, 224, 231, and 253, which are historic resources in the potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District. This demolition would result in a significant impact because the proposed actions would materially alter in an adverse manner those physical characteristics of an historical resource that convey its historical significance and that justify its eligibility for inclusion in the CRHR. Implementation of mitigation measures MM CP-1b.1 and MM CP-1b.2 would reduce those impacts; however, the demolition of historic resources would not be reduced to a less-than-significant level. Therefore, Project effects on these historical resources would be a significant unavoidable adverse impact. Chapter VI (Alternatives) analyzes Alternative 4 (Reduced CP-HPS Phase II Development, HPS Phase II Stadium, No State Parks Agreement, and Without the Yosemite Slough Bridge). Alternative 4 would include rehabilitation and reuse of Buildings 211, 224, 231, and 253 and retention of Building 208 as a cultural landscape element in the potential Hunters Point Commercial Dry Dock and Naval Shipyard Historic District. Chapter VI also contains an analysis of Subalternative 4A (CP-HPS Phase II Development Plan with Historic Preservation), which would include rehabilitation and reuse of Buildings 211, 224, 231, and 253, while keeping all other components of the Project the same.

Impact CP-2a: Change in Significance of Archaeological Resources

Impact of Candlestick Point

Impact CP-2a **Construction at Candlestick Point would not result in a substantial adverse change in the significance of archaeological resources, including prehistoric Native American, Chinese fishing camp, and maritime-related archaeological remains. (Less than Significant with Mitigation) *[Criterion J.b]***

The Project archaeological research has found that archaeological resources expected to be found on the Project site could have important research value and would, therefore, be legally significant under CEQA. Examples of research themes that have been proposed to which expected archaeological resources could contribute significant data include *(i)* the spatial organization and historical development of Chinese fishing

camps; *(ii)* effects, adaptations, and resistance of the fishing camps to anti-Chinese fishing legislation (1885-1930s); *(iii)* spatial organization of shipyards and development of local traditions of boat building technology, including that of the scow schooner and Chinese junks; *(iv)* the development, changing function, and inter-settlement relationships of prehistoric shell mounds; *(v)* comparative spatial organization of shell mound sites; *(vi)* changes in prehistoric faunal and biotic exploitation practices; *(vii)* prehistoric changes in social stratification; and *(viii)* the relationship between Hunters Point-Bayview and South of Market area prehistoric settlements. The Project could also disturb potential Native American burial sites of symbolic and cultural importance to present-day Native American tribes and representatives. Any potential archeological resources, e.g., CA-SFR-9, fishing camps, that are covered by existing development will remain covered and unavailable unless the site is redeveloped.

Mitigation measure MM CP-2a would reduce potential adverse effects of construction-related activities to archaeological resources at Candlestick Point to less-than-significant through implementation of the Project Archaeological Research Design and Treatment Plan.

MM CP-2a *Mitigation to Minimize Impacts to Archaeological Resources at Candlestick Point. Based on a reasonable presumption that archaeological resources may be present within the Project site, the following measures shall be undertaken to avoid any potentially significant adverse effect from the Project on buried or submerged historical resources.*

Overview: The Project Applicant shall retain the services of a qualified archaeological consultant having expertise in California prehistoric and urban historical archeology. The archaeological consultant shall undertake an archaeological testing program as specified herein. In addition, the archaeological consultant shall be available to conduct an archaeological monitoring and/or data recovery program if required pursuant to this measure. The archaeological consultant's work shall be conducted in accordance with this measure and with the requirements of the Project Archaeological Research Design and Treatment Plan (Archeo-Tec. Archaeological Research Design and Treatment Plan for the Bayview Waterfront Project, San Francisco, California, 2009) at the direction of the City's Environmental Review Officer (ERO). In instances of inconsistency between the requirement of the Project Archaeological Research Design and Treatment Plan and of this archaeological mitigation measure, the requirement of this archaeological mitigation measure shall prevail. All plans and reports prepared by the consultant as specified herein shall be submitted first and directly to the ERO for review and comment, and shall be considered draft reports subject to revision until final approval by the ERO. Archaeological monitoring and/or data recovery programs required by this measure could suspend construction of the Project for up to a maximum of four weeks. At the direction of the ERO, the suspension of construction can be extended beyond four weeks only if such a suspension is the only feasible means to reduce potential effects on a significant archaeological resource as defined in CEQA Guidelines Section 15064.5(a)(c) to a less-than-significant level.

Archaeological Testing Program: The archaeological consultant shall prepare and submit to the ERO for review and approval an archaeological testing plan (ATP). The archaeological testing program shall be conducted in accordance with the approved ATP. The ATP shall identify the property types of the expected archaeological resource(s) that potentially could be adversely affected by the Project, the testing method to be used, and the locations recommended for testing. The purpose of the archaeological testing program will be to determine to the extent possible the presence or absence of archaeological resources and to identify and to evaluate whether any archaeological resource encountered on the site constitutes an historical resource under CEQA.

At the completion of the archaeological testing program, the archaeological consultant shall submit a written report of the findings for submittal to the ERO. If, based on the archaeological testing program, the archaeological consultant finds that significant archaeological resources may be present, the ERO (in consultation with the archaeological consultant) shall determine if additional measures are warranted. Additional measures that may be undertaken include, but are not necessarily limited to, additional archaeological testing, archaeological monitoring, and/or an archaeological data recovery program. If the ERO determines that a significant archaeological resource is present and that the resource could be adversely affected by the Project, the Project Applicant shall either:

a. Re-design the Project so as to avoid any adverse effect on the significant archaeological resource; or

b. Implement a data recovery program, unless the ERO determines that the archaeological resource is of greater interpretive than research significance and that interpretive use of the resource is feasible.

Archaeological Monitoring Program: If the ERO, in consultation with the archaeological consultant, determines that an Archaeological Monitoring Program (AMP) shall be implemented, the AMP shall include the following provisions, at a minimum:

- *The archaeological consultant, Project Applicant, and ERO shall meet and consult on the scope of the AMP prior to the commencement of any Project-related soils disturbing activities. The ERO, in consultation with the archaeological consultant, shall determine what Project activities shall be archaeologically monitored. In most cases, any soils- disturbing activities, such as demolition, foundation removal, excavation, grading, utilities installation, foundation work, driving of piles (foundation, shoring, etc.), and site remediation, shall require archaeological monitoring because of the risk these activities pose to potential archaeological resources and to their depositional context.*
- *The archaeological consultant shall train all Project construction personnel who could reasonably be expected to encounter archaeological resources of the expected resource(s), how to identify the evidence of the expected resource(s), and the appropriate protocol in the event of apparent discovery of an archaeological resource.*
- *The archaeological monitor(s) shall be present on the Project site according to a schedule agreed upon by the archaeological consultant and the ERO until the ERO has, in consultation with the archaeological consultant, determined that Project construction activities could have no effects on significant archaeological deposits.*
- *The archaeological monitor shall record and be authorized to collect soil samples and artifactual/ecofactual material as warranted for analysis.*
- *If an intact archaeological deposit is encountered, all soil-disturbing activities in the vicinity of the deposit shall cease. The archaeological monitor shall be authorized to temporarily halt demolition/excavation/pile driving/construction activities and equipment until the deposit is evaluated. If, in the case of pile driving activity (foundation, shoring, etc.), the archaeological monitor has cause to believe that the pile driving activity may affect an archaeological resource, the pile driving activity shall be terminated until an appropriate evaluation of the resource has been made in consultation with the ERO. The archaeological consultant shall immediately notify the ERO of any encountered archaeological deposit. The archaeological consultant shall make a reasonable effort to assess the identity, integrity, and significance of the encountered archaeological deposit and present the findings of this assessment to the ERO as expeditiously as possible.*

Whether or not significant archaeological resources are encountered, the archaeological consultant shall submit a written report of the findings of the monitoring program to the ERO.

Archaeological Data Recovery Program: The archaeological data recovery program shall be conducted in accord with an Archaeological Data Recovery Plan (ADRP). The archaeological consultant, Project Applicant, and ERO shall meet and consult on the scope of the ADRP prior to preparation of a draft ADRP. The archaeological consultant shall submit a draft ADRP to the ERO. The ADRP shall identify how the proposed data recovery program will preserve the significant information the archaeological resource is expected to contain. That is, the ADRP will identify what scientific/historical research questions are applicable to the expected resource, what data classes the resource is expected to possess, and how the expected data classes would address the applicable research questions. Data recovery, in general, should be limited to the portions of the historical property that could be adversely affected by the Project. Destructive data recovery methods shall not be pursued if nondestructive methods are practical.

The scope of the ADRP shall include the following elements:

- *Field Methods and Procedures. Descriptions of proposed field strategies, procedures, and operations.*
- *Cataloguing and Laboratory Analysis. Description of selected cataloguing system and artifact analysis procedures.*
- *Discard and Deaccession Policy. Description of and rationale for field and post-field discard and deaccession policies.*
- *Interpretive Program. Consideration of an on-site/off-site public interpretive program during the course of the archaeological data recovery program.*
- *Security Measures. Recommended security measures to protect the archaeological resource from vandalism, looting, and other potentially damaging activities.*
- *Final Report. Description of proposed report format and distribution of results.*
- *Curation. Description of the procedures and recommendations for the curation of any recovered data having potential research value, identification of appropriate curation facilities, and a summary of the accession policies of the curation facilities.*

Human Remains and Associated or Unassociated Funerary Objects: The treatment of human remains and associated or unassociated funerary objects discovered during any soil-disturbing activity shall comply with applicable state and federal laws. This shall include immediate notification of the Coroner of the City and County of San Francisco and in the event of the Coroner's determination that the human remains are Native American remains, notification of the California State Native American Heritage Commission (NAHC), which shall appoint a Most Likely Descendant (MLD) (PRC Sec. 5097.98). The archaeological consultant, Project Applicant, and MLD shall make all reasonable efforts to develop an agreement for the treatment of human remains and associated or unassociated funerary objects with appropriate dignity (CEQA Guidelines Sec. 15064.5(d)). The agreement shall take into consideration the appropriate excavation, removal, recordation, analysis, custodianship, curation, and final disposition of the human remains and associated or unassociated funerary objects.

Final Archaeological Resources Report: The archaeological consultant shall submit a Draft Final Archaeological Resources Report (FARR) to the ERO that evaluates the historical significance of any discovered archaeological resource and describes the archaeological and historical research methods employed in the archaeological testing/monitoring/data recovery program(s). Information that may put at risk any archaeological resource shall be provided in a separate removable insert within the final report.

Once approved by the ERO, copies of the FARR shall be distributed as follows: California Archaeological Site Survey Northwest Information Center (NWIC) shall receive one (1) copy and the ERO shall receive a copy of the transmittal of the FARR to the NWIC. The Major Environmental Analysis division of the Planning Department shall receive three copies of the FARR along with copies

of any formal site recordation forms (CA DPR 523 series) and/or documentation for nomination to the National Register of Historic Places/California Register of Historical Resources. In instances of high public interest in or the high interpretive value of the resource, the ERO may require a different final report content, format, and distribution than presented above.

This measure would reduce the potential Project impacts to CEQA-significant archaeological resources to a less-than-significant level by ensuring that an archaeological testing program is performed and that any discovered archaeological resources are appropriately handled and documented.

Impact of Hunters Point Shipyard Phase II

Impact CP-2b **Construction at HPS Phase II would not result in a substantial adverse change in the significance of archaeological resources, including prehistoric Native American resources, Chinese fishing camps, and maritime related resources. (Less than Significant with Mitigation)** ***[Criterion J.b]***

As discussed above, records indicate that three, and possibly four, prehistoric archaeological sites are located within the HPS Phase II site, including CA-SFR-11, CA-SFR-12, CA-SFR-13, and CA-SFR-14. All of the sites are reported to be shellmounds or shell midden sites.

Moreover, previous archaeological investigations have shown that prehistoric archaeological sites in the HPS Phase II site tend to be located along the original shoreline. Therefore, it is possible that Project-related construction activities may encounter previously unknown archaeological resources. The Project could also disturb potential Native American burial sites of symbolic and cultural importance to present-day Native American tribes and representatives.

Two possible locations for a Chinese fishing camp are identified in HPS. By 1910 five of the nineteen remaining Chinese fishing camps were located at Hunters Point. At least eleven fishing camps were observed along Hunters Point shoreline in the 1930s.

Hunters Point had numerous maritime-related industries, including drydocks and boarding houses. In addition, there were several historically documented large offshore "rocks" that presented navigational hazards. Therefore, it is possible that buried shipwrecks may occur within the HPS Phase II site.

Any potential archeological resources, e.g., fishing camps, that are covered by existing development will remain covered and unavailable unless the site is redeveloped. Mitigation measure MM CP-2a would reduce the potentially significant effects of construction-related activities to the archaeological resources in the HPS Phase II site (described above) to a less-than-significant level by mitigating for the permanent loss of the adversely affected archaeological resources through implementation of the *Archaeological Research Design and Treatment Plan for the Bayview Waterfront Project, San Francisco, California*. This measure would reduce the impact to a less-than-significant level by ensuring that an archaeological testing program is performed and that any discovered resources are appropriately handled, and documented.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact CP-2 **Construction activities associated with the Project would not result in a substantial adverse change in the significance of archaeological resources, including prehistoric Native American resources, Chinese fishing camps, and maritime related resources. (Less than Significant with Mitigation) *[Criterion J.b]***

As discussed above, the Project site is expected to contain subsurface archaeological resources from the Native American, Chinese fishing village, prehistoric, and maritime development periods, including, but not limited to, CA-SFR-9, CA-SFR-11, CA-SFR-12, CA-SFR-13, and CA-SFR-14. Any potential archeological resources, e.g., fishing camps, that are covered by existing development will remain covered and unavailable unless the site is redeveloped. Construction activities associated with the Project could disturb those archaeological resources, and result in potentially significant impacts. The Project could also disturb potential Native American burial sites of symbolic and cultural importance to present-day Native American tribes and representatives. Refer to Impact CP-2a and Impact CP-2b and associated discussions, above. Mitigation measure MM CP-2a would reduce the Project potentially significant effects on archaeological resources to a less-than-significant level through implementation of the *Archaeological Research Design and Treatment Plan for the Bayview Waterfront Project, San Francisco, California*.

Impact CP-3a: Change in Significance of Paleontological Resources

Impact of Candlestick Point

Impact CP-3a **Construction at Candlestick Point would not result in a substantial adverse change in the significance of a paleontological resource. (Less than Significant with Mitigation) *[Criterion J.d]***

As discussed above, sedimentary rocks of the Franciscan Complex have a low sensitivity to impacts from Project construction. Sedimentary rocks of the Franciscan Complex have produced significant fossils important for understanding the age, depositional environments, and tectonic history of the San Francisco area and additional fossil remains discovered in rocks of the Franciscan Complex during Project construction could be scientifically important and significant. Although no fossils have been reported from the Project site, the presence of Franciscan sedimentary rocks (chert, sandstone, shale, and greenstone) on Candlestick Point in the Project site indicates the possibility of fossils being discovered during construction-related excavation.

Using Society for Vertebrate Paleontology (SVP) criteria, undifferentiated Pleistocene sediments, which may encompass some of the Colma Formation, have a high sensitivity to impacts from Project construction. Fossil fragments from these sediments have been recovered near Islais Creek northwest of the Project site. The presence of these sediments southwest of the stadium on Candlestick Point in the Project site indicates the possibility of fossils being discovered during construction-related excavation.

Using SVP criteria, the colluvium (slope debris, minor landslides), and artificial fill located within the Project site is not expected to have sensitivity to impacts from Project construction because it is not likely that artificial fill would contain paleontological resources; however, the Bay mud underlying portions of the fill at depth is expected to have a high sensitivity because it is possible, and even likely, that those

materials would contain paleontological resources. Fossil fragments from the Bay mud have been recovered near Islais Creek northwest of the Project site. The presence of the Bay mud under the fill around Candlestick Point and south of South Basin in the Project site indicates the possibility of fossils being discovered during construction-related excavation.

To reduce a potentially significant impact on paleontological resources to a less-than-significant level, the following mitigation measure shall be implemented:

MM CP-3a *Paleontological Resources Monitoring and Mitigation Program: The Project Applicant shall retain the services of a qualified paleontological consultant having expertise in California paleontology to design and implement a Paleontological Resources Monitoring and Mitigation Program (PRMMP). The PRMMP shall include a description of when and where construction monitoring would be required; emergency discovery procedures; sampling and data recovery procedures; procedures for the preparation, identification, analysis, and curation of fossil specimens and data recovered; preconstruction coordination procedures; and procedures for reporting the results of the monitoring program.*

The PRMMP shall be consistent with the Society for Vertebrate Paleontology (SVP) Standard Guidelines for the mitigation of construction-related adverse impacts to paleontological resources and the requirements of the designated repository for any fossils collected. During construction, earth-moving activities shall be monitored by a qualified paleontological consultant having expertise in California paleontology in the areas where these activities have the potential to disturb previously undisturbed native sediment or sedimentary rocks. Monitoring need not be conducted in areas where the ground has been previously disturbed, in areas of artificial fill, in areas underlain by nonsedimentary rocks (serpentinite, greenstone), or in areas where exposed sediment would be buried, but otherwise undisturbed.

The consultant's work shall be conducted in accordance with this measure and at the direction of the City's Environmental Review Officer (ERO). Plans and reports prepared by the consultant shall be submitted first and directly to the ERO for review and comment, and shall be considered draft reports subject to revision until final approval by the ERO. Paleontological monitoring and/or data recovery programs required by this measure could suspend construction of the Project for up to a maximum of four weeks. At the direction of the ERO, the suspension of construction can be extended beyond four weeks only if such a suspension is the only feasible means to reduce potential effects on a significant paleontological resource as previously defined to a less-than-significant level.

The SVP considered scientific recovery, preparation, identification, determination of significance, and curation to mitigate potentially significant impacts to paleontological resources adequately in most circumstances. Mitigation measure MM CP-3a would reduce the effects of construction-related activities to paleontological resources in the Candlestick Point area to a less-than-significant level by mitigating for the permanent loss of the adversely affected resources through implementation of a Paleontological Resources Monitoring and Mitigation Program.

Impact of Hunters Point Shipyard Phase II

Impact CP-3b **Construction at HPS Phase II would not result in a substantial adverse change in the significance of a paleontological resource. (Less than Significant with Mitigation) *[Criterion J.d]***

As discussed above, sedimentary rocks of the Franciscan Complex have a low sensitivity to impacts from Project construction. Sedimentary rocks of the Franciscan Complex have produced significant fossils

important for understanding the age, depositional environments, and tectonic history of the San Francisco area and additional fossil remains discovered in rocks of the Franciscan Complex during Project construction could be scientifically important and significant. Although no fossils have been reported from the Project site, the presence of Franciscan sedimentary rocks (shanstone, shale, chert, and greenstone) on the flanks of Hunters Point in the Project site indicates the possibility of fossils being discovered during construction-related excavation.

Using SVP criteria, the colluvium (slope debris, minor landslides), serpentinite, and artificial fill located within the Project site is not expected to have sensitivity to impacts from Project construction because it is not likely that artificial fill would contain paleontological resources; however, the Bay mud underlying portions of the fill at depth is expected to have a high sensitivity because it is possible, and even likely, that those materials would contain paleontological resources. Fossil fragments from the Bay mud have been recovered near Islais Creek northwest of the Project site. The presence of the Bay mud under the fill around Hunters Point in the Project site indicates the possibility of fossils being discovered during construction-related excavation.

Mitigation measure MM CP-3a would reduce the effects of construction-related activities to paleontological resources at HPS Phase II to a less-than-significant level by mitigating for the permanent loss of the adversely affected resources through implementation of a Paleontological Resources Monitoring and Mitigation Program.

To reduce any potential significant impact on paleontological resources to a less-than-significant level, mitigation measure MM CP-3a would be implemented. The SVP considered scientific recovery, preparation, identification, determination of significance, and curation to mitigate impacts to paleontological resources adequately in most circumstances. Consequently, the implementation of this measure would reduce the potentially significant adverse environmental impact of Project-related ground disturbance on paleontological resources to a less-than-significant level.

Impact of Yosemite Slough Bridge Construction Activities

Impact CP-3c **Construction of the Yosemite Slough bridge, shoreline improvements, and the marina improvements activities, including in-water activities, would not result in a substantial adverse change in the significance of a paleontological resource. (Less than Significant with Mitigation) *[Criterion J.d]***

Using SVP criteria, the artificial fill located within the Project site is not expected to have sensitivity to impacts from Project construction because it is not likely that artificial fill would contain paleontological resources; however, the Bay mud underlying portions of the fill at depth is expected to have a high sensitivity because it is possible, and even likely, that those materials would contain paleontological resources. As discussed above, fossil fragments from the Bay mud have been recovered near Islais Creek northwest of the Project site. The presence of the Bay mud under the fill in the vicinity of Yosemite Slough and the marina in the Project site indicates the possibility of fossils being discovered during construction-related excavation associated with the Yosemite Slough bridge, shoreline improvements, and the marina improvements.

Mitigation measure MM CP-3a, as described previously, would reduce the potentially significant effects of construction-related activities to paleontological resources in in-water and off-site areas to a less-than-significant level by mitigating for the permanent loss of the adversely affected resources through implementation of a Paleontological Resources Monitoring and Mitigation Program.

Impact of Yosemite Slough Bridge Pile Driving

Impact CP-3d **Pile driving associated with construction of the Yosemite Slough bridge, shoreline improvements, and the marina improvements would not result in a substantial adverse change in the significance of a paleontological resource. (Less than Significant with Mitigation) *[Criterion J.d]***

Construction of the Yosemite Slough bridge, shoreline improvements, and the marina improvements would involve the installation of about 375 new pilings. Details of the installation program are not yet available, but it is probable that there would be disruption of sediments in the shallow-water portions of the driving sites. Using SVP criteria, the artificial fill located within the Project site is not expected to have sensitivity to impacts from Project construction because it is not likely that artificial fill would contain paleontological resources; however, the Bay mud underlying portions of the fill at depth is expected to have a high sensitivity because it is possible, and even likely, that those materials would contain paleontological resources. As discussed above, fossil fragments from the Bay mud have been recovered near Islais Creek northwest of the Project site. The presence of the Bay mud under the fill in the vicinity of Yosemite Slough and the marina in the Project site indicates the possibility of fossils being discovered during construction-related excavation.

Mitigation measure MM CP-3a, as described previously, would reduce the potentially significant effects of construction-related activities to paleontological resources in in-water and off-site areas to a less-than-significant level by mitigating for the permanent loss of the adversely affected resources through implementation of a Paleontological Resources Monitoring and Mitigation Program.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact CP-3 **Construction activities associated with the Project would not result in a substantial adverse change in the significance of a paleontological resource. (Less than Significant with Mitigation) *[Criterion J.d]***

Refer to Impact CP-3a through Impact CP-3d and associated discussions, above. As discussed above, the presence of sedimentary rocks and Bay mud in the Project site indicates the possibility of fossils being discovered during construction-related excavation, or marina, or Yosemite Slough bridge construction.

Mitigation measure MM CP-3a, as described previously, would reduce the potentially significant effects of construction-related activities to paleontological resources throughout the Project site to a less-than-significant level by mitigating for the permanent loss of the adversely affected resources through implementation of a *Paleontological Resources Monitoring and Mitigation Program*.

Cumulative Impacts

The cumulative analysis for impacts on cultural and paleontological resources considers a broad regional system of which these resources are a part. The cumulative context for historical resources is the San

Francisco Bay Area Peninsula (Peninsula), which contains both San Francisco and San Mateo counties where common patterns of historic-era settlement have occurred. The cumulative context for archaeological resources and human remains is the northern tip of the San Francisco peninsula where Native American archaeological sites, Chinese fishing camps, and maritime activities were concentrated. The cumulative context for paleontological resources is the Quaternary deposits of the Bayside portions of the San Francisco Bay Area and Franciscan Complex bedrock throughout the Bay Area.

Historical Resources

Urban development that has occurred over the past several decades along the Peninsula, specifically along the Bay with regards to marine/port type resources has resulted in the demolition and alteration of significant historical resources, and it is reasonable to assume that present and future development activities will continue to result in impacts on significant historical resources, including residential, commercial, and civic properties, that are listed or eligible for listing on national, state, or local registers.

Federal, state, and local laws protect historical resources in most instances, but it is not always feasible to protect historical resources, particularly when preservation in place would frustrate implementation of projects. For this reason, the cumulative effects of development along the Peninsula on historical resources are considered significant.

San Francisco and other bay-side communities along the Peninsula contain numerous known resources of historic and cultural value. In addition, undocumented buildings or structures of historic age which qualify as historical resources pursuant to CEQA may also exist within the City. Enforcement of existing local codes and policies, including the Urban Design Element of the San Francisco General Plan, aimed at the preservation and protection of historical resources would ensure that development activities resulting from implementation of the Project would undergo rigorous review to determine impacts on historical resources in accordance with CEQA and would encourage the avoidance of significant impacts through explicitly defined actions and development incentives. Nonetheless, because existing and proposed City policies do not explicitly prohibit demolition or alteration of historic-period buildings or structures, it is possible that development activities resulting from implementation of the Project could cause a substantial adverse change in the significance of a historical resource. Because the Project would adversely affect significant historical resources that are unique and non-renewable members of finite classes, even with the implementation of mitigation measures MM CP-1b.1 and MM CP-1b.2, the Project's incremental contribution to these cumulative effects would itself be potentially cumulatively considerable, and thus significant and unavoidable.

Archaeological Resources

Any potential archeological resources such as fishing camps that are covered by existing development will remain covered and unavailable unless the site is redeveloped. Past urban development that has occurred along the Peninsula has resulted in damage and destruction of archaeological resources. For this reason, the cumulative effects of development along the Peninsula and surrounding the Bay to archaeological resources are considered significant. In recent years, CEQA has required that development projects identify the potential for archaeological resource impacts and mitigate those impacts (CEQA Section 21083.2 and CEQA Guidelines 15064.5). Consequently, development in the recent past has not, and development in the present and the reasonably foreseeable future would not contribute to a significant adverse cumulative

archaeological resource impact. Similarly, with implementation of mitigation measure MM CP-2a, the Project would have a less-than-significant impact on archaeological resources that are unique and non-renewable members of finite classes, and the Project's incremental contribution to these cumulative effects would not be cumulatively considerable, as it would not contribute to a loss of valuable resources.

Paleontological Resources

Urban development that has occurred over the past several decades in Quaternary deposits of the Bayside portions of the San Francisco Bay Area and Franciscan Complex bedrock throughout the Bay Area has damaged paleontologically sensitive rock and sediment formations with the resultant loss of paleontological resources. Federal, state, and local laws protect paleontological resources in many instances, but protection is not always feasible, particularly when preservation in place would frustrate implementation of proposed development. For this reason, the cumulative effects of development in Quaternary deposits and Franciscan bedrock on paleontological resources are considered significant. In recent years, CEQA has required that development projects identify the potential for paleontological resources and mitigate those impacts. Consequently, many development projects in the recent past have not, and many development projects in the present and reasonably foreseeable future would not contribute to a significant adverse cumulative paleontological resource impact. Similarly, with implementation of mitigation measure MM CP-3a, the Project would have a less-than-significant impact on paleontological resources that are non-renewable members of finite classes, and the Project's incremental contribution to these cumulative effects would not be cumulatively considerable, as it would not contribute to a loss of these valuable resources.

Human Remains

As previously discussed, the Peninsula is known to be rich in subsurface archaeological resources in certain settings, and the archaeological record indicates a high level of habitation/seasonal habitation and resource use by Native Americans. Although past projects have contributed to a significant loss of these resources, in recent years CEQA has required that development projects with the potential to affect human remains must implement procedures in order to ensure their appropriate treatment (CEQA Guidelines Section 15064.5). Consequently, development projects in the recent past have not, and development projects in the present and reasonably foreseeable future would not contribute to a significant adverse cumulative human remains impact. Similarly, with implementation of mitigation measure MM CP-2a, the Project would have a less-than- significant impacts on cultural resources that are unique and non-renewable members of finite classes, and the Project's incremental contribution to these significant cumulative impacts would not be cumulatively considerable, as it would not contribute to a loss of significant resources.

SECTION III.K HAZARDS AND HAZARDOUS MATERIALS

III.K.1 Introduction

This section considers the range and nature of foreseeable hazardous materials and physical hazards impacts resulting from construction and occupancy of the Project. It identifies the primary ways these hazards could expose people and the environment to various health and safety risks associated with those hazards. This section describes the available information about hazardous materials in soil, sediment, surface water, and groundwater at the Project site and evaluates the potential for construction and occupancy of the Project to affect, or be affected by, environmental contamination associated with historic and current land uses within the Project site. It provides basic definitions of terms, and background on physical conditions. Historic and current land uses are summarized in this section, based on reports prepared by the Navy for the HPS Phase II, environmental assessments and documents that describe conditions in Candlestick Point, and a review of regulatory databases. In addition, a description of regulatory requirements that provide for the management of soil or groundwater contamination on the Project site is provided. Due to the unique contamination conditions and remediation efforts at HPS Phase II, portions of the impact analysis are presented separately from the analysis of Candlestick Point.

This section also describes the nature and extent of routine hazardous materials used in existing land uses in the Project site (e.g., production, distribution, and repair [PDR] uses and mixed-use development), and the potential for upset and accident conditions in which hazardous materials could inadvertently be released. The impact analysis identifies how proposed new land uses would introduce additional operational components (e.g., Research & Development [R&D]) that would increase the types and amounts of hazardous materials routinely used, stored, or transported to, from, and within the Project site, and the extent to which existing and future populations could be exposed to hazardous materials.

Other elements of hazardous materials exposure and potential risks to human health and the environment are air emissions. Sources of hazardous or toxic air emissions include, but are not limited to: processes (e.g., laboratory fume hood exhaust in R&D uses); vehicle use (diesel particulate emissions from exhaust); and proximity to existing or relocated sources of diesel or other toxic air emissions such as freeways and railroads and off-site industries and businesses. Impacts related to toxic air contaminants, including the release of diesel particulate matter from construction truck trips and/or delivery truck trips (when the haul routes are located within one-quarter mile of an existing or proposed school) are identified in Section III.H (Air Quality). The Project's proximity to air traffic and the potential for air safety hazards is evaluated in this section, along with an analysis of potential fire hazards and emergency response/access issues associated with the proposed intensification of land uses. Other safety hazards, such as earthquakes, are addressed in Section III.L (Geology and Soils). Flooding and sea level rise are addressed in Section III.M (Hydrology and Water Quality).

The use of hazardous materials in existing development, as well as any proposed future activities involving hazardous materials, along with the generation of hazardous wastes in the land uses, is governed by numerous federal, state, and local laws and regulations, which are summarized in this section. This section identifies both Project level and cumulative environmental impacts, as well as feasible mitigation measures that could reduce or avoid the identified impacts.

Scope of Analysis

Hazardous Materials Contamination Associated with Historic and Current Uses

There are substantial ongoing remediation programs at known hazardous material release sites at portions of the Project site from former Navy operations, Triple A Machine Shop, Inc., and/or its lessees throughout HPS Phase II. These are the only known hazardous material release sites requiring remediation at the Project site; there are no known hazardous material release sites requiring remediation at Candlestick Point, or at locations where off-site improvements are proposed, based on the results of investigations to date and a review of government agency databases. For Candlestick Point and off-site locations, however, the analysis recognizes the potential for previously unknown contamination to be encountered, and recommends mitigation measures to address that potential.

The remediation program at HPS Phase II is being carried out under the *Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA) and through a 1992 Federal Facilities Agreement (FFA) between the Navy and federal and state regulatory agencies. This ongoing remedial program is required to implement all remedial actions necessary to protect human health and the environment from risks associated with hazardous materials released into soil or groundwater, in consideration of the uses contemplated by the Project. As was the case in the Final Environmental Impact Report for HPS dated February 8, 2000,[273] and the Addendum to that FEIR dated November 19, 2003,[274] which supported the approval of the Phase 1 development at HPS, these ongoing remediation activities are not part of the Project. Thus, the goal of this EIR is not to assess the adequacy or impacts of the Navy's remediation actions. The relevant environmental regulatory agencies would require performance of these remedial activities regardless of whether this Project or any other development proposals were proceeding. Potential environmental effects of the remedial activities, i.e., of soil excavation, soil transport, and operation of treatment systems, have been, and will continue to be, evaluated by the Navy and regulatory agencies in conjunction with the approval process for specific remedial actions, and appropriate environmental controls have been, and will continue to be, incorporated into the design and implementation of those remedial actions. Therefore, although this EIR evaluates the potential for construction and occupancy of the Project to affect, or be affected by, hazardous materials release sites, it does not evaluate the potential impacts of the specific remedial activities conducted as part of these ongoing programs. However, this EIR does evaluate the potential impacts of certain limited remedial activities proposed to be conducted in conjunction with development activities, as described below.

A copy of this document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.
[274] San Francisco Redevelopment Agency and Planning Department, *Hunters Point Shipyard Phase I Addendum to Final Environmental Impact Report, Hunters Point Shipyard Reuse*, November 19, 2003. A copy of this document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

Proposed Land Uses—Operational Impacts

The Project Description identifies proposed land uses, but the specific businesses or activities that could operate in the Project are not known at this time. The analysis assumes nearly all Project uses would involve the routine use of hazardous materials at varying levels, including uses at existing PDR and mixed-use land uses, and that there is the potential that such use could result in a release of hazardous materials. In each case, the potential hazards and the risks they would pose to people or the environment would depend on what materials would be used, where the materials would be used and stored, how they would be used, and who would use them. Quantification of precise amounts of additional hazardous materials use associated with new proposed uses is not practical at this stage of Project development. Therefore, the analysis qualitatively evaluates broad categories of hazardous materials use, ranging from R&D in which a wide variety of hazardous materials would be used, to facilities such as the proposed stadium, where fuels and maintenance products would comprise the majority of hazardous materials, to smaller-scale users, such as artists' studios and households. For purposes of the analysis, compliance with existing federal, state, and local laws and regulations pertaining to hazardous materials management would be sufficient to minimize health and safety risks, because these laws and regulations have been designed to protect health and safety and are enforced by state and local agencies.

The analysis of air traffic hazards is not addressed in detail in this EIR because the Project is not within hazard zones for any airport.

Regulatory Requirements and Mitigation Measures

HPS Phase II

All necessary remedial actions at HPS Phase II required by CERCLA, the FFA, or other applicable law must be completed to the satisfaction of the relevant regulatory agencies, and those agencies must determine that the site is suitable for its intended use, whether those remedial activities take place before or after the Navy transfers ownership of the property. The mitigation measures set forth in this section require the Project to be consistent with any requirements imposed as part of these remediation programs, and the federal, state, and local laws governing those remediation programs. For example, if such laws require institutional controls such as land use covenants that prohibit certain activities or types of land use on portions of the Project site or require the preparation and implementation of a Risk Management Plan (RMP), the mitigation measures set forth below impose the same requirements. Similarly, the mitigation measures require the Project to be implemented consistent with the terms of any property transfer document, e.g., if the Navy transfers ownership or leases portions of HPS Phase II prior to completion of remedial activities, the mitigation measures require the transferee to comply with all applicable activity and use restrictions set forth in the lease or deed.

Candlestick Point

Before permits are issued from the San Francisco Department of Building Inspection for development activities at the portions of Candlestick Point that are bayward of the 1851 high tide line (and, therefore, constructed on "Bay Fill" material), the Project Applicant must prepare a site history and soil sampling work plan, conduct soil sampling and analysis and, if found to be necessary, propose and implement site

mitigation measures[275] under the supervision of the San Francisco Department of Public Health as required by Article 22A of the *San Francisco Health Code* (sometimes called the Maher Ordinance). Mitigation measures identified in this EIR that are consistent with Article 22A (site mitigation measure requirements) are included below. No potentially significant impacts from exposure to hazardous materials release sites have been identified at the portions of Candlestick Point landward of the 1851 high tide line (i.e., in bedrock areas and/or areas containing soil deposited by natural means), based on publicly available information. However, because there is a potential that previously unidentified (or unknown) contaminated sites could be encountered during development activities (either within the Project site or at off-site improvement locations), this EIR identifies mitigation measures consistent with applicable federal and state regulatory requirements to prevent those activities from adversely affecting human health and the environment.

Certain other types of hazardous materials that may be present at the site (e.g., asbestos and lead-based paint in building materials, or naturally occurring asbestos in bedrock) are not addressed by the remediation programs described above but instead are addressed by mitigation measures requiring actions consistent with applicable regulatory requirements are provided.

Hazardous Materials Use

As a result of the health and safety risks associated with the use of hazardous materials, hazardous materials use, storage, and disposal are subject to numerous laws and regulations at various levels of government. These laws and regulations are identified in this Section. In most cases, the laws and regulations pertaining to hazardous materials management are sufficient to minimize risks to human health and the environment, except where site-specific conditions warrant additional consideration. The impact analysis identifies areas where impacts related to hazardous materials during Project occupancy may, nonetheless, be potentially significant. In these cases, feasible mitigation measures are identified.

Hazardous Materials Basic Concepts and Terms

Some of the key terms used in the management of hazardous materials and the context within which they apply to sites where contaminants have been identified in soil or groundwater are presented below. Additional terminology is provided in the EIR glossary in Chapter VIII (Acronyms/Abbreviations and Glossary).

- A "hazardous material" is any material that, because of its quantity, concentration, or physical, or chemical characteristics, poses a significant present or potential hazard to human health and safety or to the environment if released into the workplace or the environment. Hazardous materials include, but are not limited to, hazardous substances, hazardous waste, and any material that a handler or the administering agency has a reasonable basis for believing that it would be injurious to the health and safety of persons or harmful to the environment if released into the workplace or the environment (*California Health and Safety Code*, Section 25501).
- A "hazardous materials release site" refers to any area, location, or facility where a hazardous material has been released or threatens to be released to the environment.

[275] The "site mitigation measures" required under Article 22A, Section 1228 are identified separately and independently of the CEQA process.

- "Remedial action" or "remediation" refers to actions required by federal, state, or local laws, ordinances, or regulations necessary to prevent, minimize, or mitigate damage that may result from the release or threatened release of a hazardous material. These actions include site cleanup, monitoring, testing, and analysis of site conditions, site operation and maintenance, and placing conditions or restrictions on the land use of the site upon completion of remedial actions. This section describes those actions and it is assumed that those actions would appropriately prevent, minimize, or mitigate potential environmental impacts.

The risk to human health and the environment is determined by the probability of exposure to hazardous material(s) and the severity of harm such exposure would pose. That is to say, the likelihood and means of exposure, in addition to the inherent toxicity of a material, are used to determine the degree of risk to human health or the ecological environment. For example, a high probability of exposure to a low toxicity chemical would not necessarily pose an unacceptable human health or ecological risk, whereas a low probability of exposure to a very high toxicity chemical might. Methodologies have been established by the US Environmental Protection Agency (USEPA), which are also used at the state level, to quantify that risk. The quantified risk levels are one of several elements used in the decision-making process to determine how that risk should be managed.

III.K.2 Setting

This Setting describes the nature and extent of hazardous materials release sites within the Candlestick Point and HPS Phase II sites, along with the current status of investigation and cleanup efforts in those sites. It also identifies Project-wide hazards and hazardous materials conditions such as naturally occurring asbestos, hazardous materials use, and conditions at off-site improvement locations.

Current Conditions at Candlestick Point

As described below, there are no known hazardous materials release sites requiring remediation at Candlestick Point.

Historic Uses at Candlestick Point

Nearly all the land that presently encompasses Candlestick Point was originally submerged beneath the waters of the Bay. The only non-submerged land was Candlestick Point, which rose steeply from the South Basin and was part of the northeastern slope of Bayview Hill.

Historic uses in Candlestick Point were open space with some limited industrial activities. The stadium was constructed in the late 1950s. Candlestick Point State Recreation Area (CPSRA) was established in 1974 to construct a 154-acre park along the eastern shoreline.[276]

Areas of the San Francisco Bay shoreline that border Candlestick Point (as well as HPS Phase II) historically consisted of marshland with tidal sloughs. Beginning in the 1850s, the shallow margins of the Bay were filled to extend the shoreline, and the fill activities have altered the natural shoreline. The majority

[276] Department of Parks and Recreation, *Candlestick Point State Recreation Area General Plan* (State Park and Recreation Commission Approval, November 1978, amended May 1987), March 1988.

of the shoreline was filled between 1906 and 1940, with the Yosemite Slough area and portions between Islais Creek and HPS Phase II filled in the 1930s to 1950s.

As with many other locations along the Bay shoreline in the City, the fill materials were primarily obtained from dune sands, quarried rock from local hillsides, industrial refuse, and building debris following the 1906 earthquake. Hazardous materials used both as standard materials of construction and in the industries that were destroyed during the 1906 fire and earthquake were commonly incorporated into the earthquake debris, which was then used as general fill and subsequently built upon during reconstruction. Because of this historical practice, the 1906 earthquake fill commonly contains hydrocarbons, heavy metals, oil and grease, and semi-volatile organic compounds. Asbestos in fireproofing materials and lead from paints may also be present. The type of fill so far identified within Candlestick Point consists primarily of clays, with some sand and gravel, except in an area south of Yosemite Slough where there is less clay and more sand, gravel and silts. The investigation discussed below indicates that debris found in the fill at Candlestick Point includes crushed concrete, red brick, foam, plastic, ceramic tiles, copper wire, porcelain, glass, and wood fragments.[277]

Alice Griffith Public Housing

The area now occupied by the Alice Griffith public housing site was first developed in 1863 as a horseracing track known as Bay View Park. By the 1880s, the site had been reclaimed by the Bay, and remained undeveloped marshland until World War II. Prior to the construction of the Alice Griffith public housing, the site was occupied by the Double Rock War Dwellings, constructed in the 1940s to house workers at the Shipyard. The site was filled and graded in the early 1960s to construct the Alice Griffith public housing. The source of the fill is unknown, but may have come from the adjacent hillside. The current Alice Griffith public housing site consists of a community of 256 units ranging in size from one to five bedrooms, paved parking, and landscaped areas that were constructed beginning in 1962.

Results of Environmental Investigations at Candlestick Point

In 1998, Geomatrix Consultants, Inc, (Geomatrix) conducted an investigation of the current site of Candlestick Park and associated parking areas, CPSRA and maintenance area, an area north of Yosemite Slough, an area southeast of Harney Way, and Hunters Point Expressway, comprising a total land area of approximately 196 acres, for the then-proposed new stadium and retail mall.[278] The investigation report noted both the presence of fill materials described above and that there were a number of documented underground storage tanks (USTs) throughout Candlestick Point, some of which have been removed along with associated soil remediation, but, as the report concluded, there may still be unknown USTs within Candlestick Point.

To determine if potential releases of hazardous materials associated with fill materials, USTs, or other unidentified sources may present an unacceptable risk to human health or the environment, Geomatrix performed an extensive soil and groundwater sampling program to collect chemical data from areas where

[277] Geomatrix, *Reference Report Summarizing Environmental Conditions Bayview Hunters Point Brownfields Pilot Project, San Francisco, California*, April 1998. Areas SE14, SE11, NE08. This document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.
[278] Ibid.

underground and above-ground storage tanks were known to previously exist, and to evaluate chemical types and concentrations in fill at depths of up to 15 feet, the depth at which excavation could occur during the previously planned redevelopment activities. Seventy-eight soil borings were advanced and 26 temporary shallow groundwater monitoring wells installed to investigate the fill areas. Two hundred and twenty soil samples were analyzed for metals, 50 soil samples were analyzed for volatile organic compounds (VOC),[279] 90 soil samples were analyzed for polycyclic aromatic hydrocarbons known as petroleum hydrocarbon constituents (PAHs), and 124 samples were analyzed for pesticides, herbicides, polychlorinated biphenyls (PCBs), and asbestos. Groundwater samples were analyzed for VOCs, total extractable petroleum hydrocarbons as diesel (TEPHd), PAHs, PCBs, pesticides, metals, and total dissolved solids.

The main chemicals detected in soils were PAH and metals (chromium, copper, lead, mercury, nickel, and zinc). PCBs and trace concentrations of chlorinated pesticides were also detected in soil. The organic compounds and metals in soil were found at various and widely disparate depths and locations. This indicated the chemicals were very likely associated with fill materials. Shallow groundwater beneath the site was found to contain low levels of a few organic compounds. A human health risk evaluation concluded that the presence of the detected chemicals in soil and shallow groundwater did not pose a significant carcinogenic or non-carcinogenic risk to future workers or visitors, nearby residents or workers, or recreational users of areas adjacent to the Bay. Compounds of potential ecologic concern (metals and pesticides) were determined to not pose a significant risk to aquatic organisms.[280]

In June 2006, MACTEC conducted a Phase I Environmental Site Assessment (ESA) for Candlestick Point; in March 2009, MACTEC updated the assessment to include the proposed Candlestick Point Center, Alice Griffith housing development, the Jamestown Avenue parcels, and the CPSRA. No releases or areas of recognized environmental conditions were observed or noted during these Phase I assessments. The 2009 Phase I ESA did note that these areas, including the Alice Griffith public housing site, were built on fill materials, so the general statements about fill materials in this section also apply to those portions of Candlestick Point.

In preparing the ESA, MACTEC conducted a site visit of the Alice Griffith site. General maintenance chemicals including paints and cleaners were observed in storage areas. No other petroleum products or hazardous materials were observed, nor was there any indication of past releases of hazardous materials. The ESA did note the potential presence of lead-based paint and the potential for asbestos-containing materials, given the age of the buildings within the Alice Griffith site.

From February 2009 through July 2009, the California Department of Parks and Recreation (DPR) conducted a trail restoration, waste, and rubble removal project at CPSRA. The project was funded by the California Integrated Waste Management Board (CIWMB) through a grant from its Solid Waste Cleanup Program. CIWMB determined that CPSRA was eligible for the program because of the damage caused by a series of fires in the early 1980s in an area of Bay Fill called the Last Rubble Disposal Area.

---

[279] A volatile organic compound (VOC) is an organic chemical that readily evaporates at temperatures normally found at the ground surface and at shallow depths.

This document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

In the context of approving a recent request to conduct geotechnical test drilling in the CPSRA, DPR staff indicated in September 2009 that, decades ago, individuals may have disposed of household hazardous waste on portions of the CPSRA. DPR does not have any files indicating that a state-regulated landfill was on-site. CIWMB staff responded to DPR staff's inquiry about the proposed test drilling by confirming that the activity was "not of regulatory significance."[281]

The scope of work at CPSRA centered around three tasks: the identification and removal of solid waste, rubble, and hazardous materials; the restoration of a few trails and access roads and the re-vegetation of some areas. Areas of CPSRA that were observed to contain hazardous materials or any soil observed to contain burn ash was sampled and tested for organic constituents. Any materials that were deemed to be hazardous were removed and disposed of in compliance with applicable law. During the rubble removal, the contractor and DPR segregated rocks that were suitable for shoreline hardening repairs and preserved all of the granite stones.

According to the California Department of Toxic Substances Control (DTSC) EnviroStor and State Water Resources Control Board (SWRCB) Geotracker online databases, there are currently no known, unremediated, or active hazardous materials release sites at Candlestick Point.[282,283]

Current Conditions at Hunters Point Shipyard

As described below, the historic uses at HPS by both the Navy and its tenants resulted in a number of hazardous materials release sites that are presently undergoing remediation by the Navy under federal law under the supervision of federal and state environmental agencies and in accordance with CERCLA. The Navy and regulatory agencies have determined that none of the areas that are accessible to tenants and visitors is a hazard to current tenants and visitors, as determined in the 2008 Finding of Suitability to Lease (FOSL) issued by the Navy.

Historic Uses at Hunters Point Shipyard

HPS is on a peninsula that extends east into the Bay. The entire HPS covers 936 acres: 496 on land and 440 under water. Maritime activities at HPS began in the nineteenth century when the first drydock was built in 1868. In 1903, a second dry-dock was built and operated by Bethlehem Steel Company. The Navy purchased HPS in 1939 and took over full operations in 1941. Significant construction began in 1941 after American entry into World War II, when the Navy began excavation of the hills surrounding the shipyard, using the resulting spoils to expand the shoreline into the Bay. Expanding the size of the shipyard through filling the Bay with soil, waste, and debris continued through the 1970s. HPS's primary mission was the repair and maintenance of ships and submarines.

After the 1946 atomic tests at Bikini Atoll in the South Pacific, contaminated target and support ships were brought to HPS for decontamination and study. In response to the new need to understand radiological issues, the Naval Radiological Defense Laboratory (NRDL) was established in 1948 at Hunters Point and

[281] Personal communication between Stephen Bachman, California Department of Parks and Recreation, and Jeff Austin, Lennar Bay Area Urban, September 28, 2009.

[283] State Water Resources Control Board Geotracker website. http://geotracker.swrcb.ca.gov (accessed June 26, 2009).

operated until 1969. Historic radiological operations also included the following: repair, use, and disposal of radioluminescent commodity items (dials, gauges, and deck markers); gamma radiography for testing of metal and welds; and laboratory calibration operations for ensuring radiation survey instrument accuracy. Additionally, Mare Island Naval Shipyard used berthing and dry-dock facilities at HPS between 1985 and 1989 for work on nuclear-powered ships. The primary radionuclides involved with these operations were tritium (hydrogen-3 [H-3]), cesium-137, radium-226, strontium-90, thorium-232, plutonium-239, americium-241, and uranium-235.

HPS was decommissioned in 1974. In 1976, the Navy leased the site to Triple A Machine Shop (Triple A), which was subsequently indicted and convicted for illegal disposal of hazardous substances at Hunters Point. In 1986, Triple A's 10-year lease expired and was not renewed. The Navy is responsible for addressing hazardous material releases resulting from Triple A's activities. Between 1986 and 1990, the Navy used Hunters Point to repair several naval vessels. In 1991, HPS was placed on the Navy's Base Realignment and Closure (BRAC) list, and its mission as a Navy shipyard ended on April 1, 1994.

Status of Environmental Investigations and Cleanup Activities

The historic operations at HPS Phase II described above are the sources of chemical and radiological contamination that resulted in the need for extensive investigation and development of remedial measures. Beginning in 1984, the Navy has undertaken a comprehensive program to address hazardous materials release sites at HPS. This program is called the "Installation Restoration Program." The property was added to the National Priorities List (NPL) in 1989 as a Superfund site pursuant to CERCLA. HPS is included on the list of hazardous materials sites compiled pursuant to California *Government Code* Section 65962.5 (the "Cortese" list).

In 1992, the Navy, the USEPA Region 9, the DTSC, and the San Francisco Bay Regional Water Quality Control Board (RWQCB) (collectively referred to as the FFA Signatories) entered into a FFA. The FFA establishes a procedural framework and schedule for the remediation of HPS. Environmental investigation and restoration activities at HPS are coordinated as prescribed in the FFA among the Navy, USEPA, and the State of California (including DTSC and RWQCB). The FFA divided the HPS facility into five contiguous geographic parcels (Parcels A, B, C, D, and E) to organize and expedite the cleanup process. A sixth parcel, the offshore area (Parcel F), was added in 1996, and another separate parcel (Parcel E-2) was created in 2004. In 2008, the Navy divided Parcel D into four parcels: D-1, D-2, UC-1, and G. Parcel UC-2 was carved out of Parcel C. Parcels UC-1 and UC-2 will serve as streets and utility corridors.[284] Figure III.K-1 (Hunters Point Shipyard Phase II Hazardous Materials Conditions) shows the locations of the Navy parcels in HPS Phase II. Table III.K-1 (Hunters Point Shipyard Navy Parcels' Relationship to Proposed Districts) shows how the HPS facility cleanup parcel designations generally correspond to the proposed district nomenclature. However, for purposes of this section, the Navy's facility parcel designations are used to describe locations.

[284] As shown in recent Navy fact sheets and report figures, it is anticipated that the Navy will carve an additional street and utility corridor, Parcel UC-3, out of Parcel E in the future.

The status of the Navy's environmental investigations and cleanup activities at each of the parcels at HPS Phase II is discussed in separate subsections below. To understand the status at each parcel, it is helpful to first have a general understanding of the process followed by the Navy pursuant to the FFA for investigating and cleaning up HPS Phase II.

Overview of the Environmental Investigation and Cleanup Process

The cleanup process under the FFA involves the preparation of an iterative series of reports documenting various investigation and remedial activities, and securing the approval of those reports from the other FFA Signatories (USEPA, DTSC, and RWQCB). Early in its implementation of the Installation Restoration Program, the Navy conducted a Preliminary Assessment and Site Identification (PA/SI) process to identify the locations at HPS requiring additional investigation and perhaps remediation. These locations were identified as "Installation Restoration Sites" (IR sites) and were designated by numbers, IR 1 through IR 78.

After the site identification process, the next step under the Navy's program is the preparation of Remedial Investigation (RI) reports for the IR sites and other locations of concern in each parcel. An RI report addresses the nature and extent of contamination at each IR site in the parcel. A Human Health Risk Assessment (HHRA) is prepared in conjunction with the RI. The HHRA identifies the contaminants that could pose a health risk under different exposure scenarios, and identifies potential numeric remediation goals. At certain sites, an Ecological Risk Assessment (ERA) is also conducted.

The next step is the preparation of a Feasibility Study (FS) for all of the IR sites requiring further action and other locations of concern in a parcel. The FS evaluates the effectiveness and cost of various remedial technologies that can be used to reduce site risk to acceptable levels. Those two steps are often combined through the preparation of a single RI/FS document. The Navy has completed the RI/FS process at all

parcels except Parcels E and E-2.[285] A draft FS has been completed for Parcel E, and a draft final RI/FS has been completed for Parcel E-2. A The Navy often does not wait for the RI/FS process to be complete before commencing physical cleanup activities. The Navy has completed numerous "time critical" (and "non-time critical") "removal actions" and "treatability pilot studies" in conjunction with its physical investigations and evaluation of alternatives for remediating the identified IR sites.

After the RI/FS process is completed, the Navy prepares a Proposed Plan (PP), which summarizes findings of the RI and proposes a preferred remedial approach for each identified IR site in a parcel based on the options evaluated in the FS. After the PP is presented to regulatory agencies and the public, the final decision selecting the remedy for the parcel is documented in a CERCLA Record of Decision (ROD), which is approved by the FFA Signatories. The CERCLA ROD takes into account public comments and community concerns and includes the Navy's response to these comments. RODs have been completed for Parcels B, D-1, UC-1, UC-2, and G. The RODs for Parcels C and D-2 are scheduled to be complete in the 2009-2010 timeframe. The ROD for Parcel F is not expected until 2012.

After the ROD is finalized, a Remedial Design document is prepared to set forth details of how the remedies identified in the ROD will be carried out. Then, the remedial actions are conducted in accordance with the specifications of the approved remedial design, e.g., groundwater treatment systems and soil vapor extraction systems are installed and operated, soil is excavated, caps are installed, land use restrictions are legally recorded, etc. In many cases, these components of the remedy have already commenced or even been completed before issuance of the ROD—as removal actions or treatability studies.

The process described above is for activities addressing hazardous substances under CERCLA. Because CERCLA excludes petroleum from its definition of "hazardous substances," the cleanup of petroleum releases from USTs or other sources is regulated under state law by the RWQCB. The petroleum cleanup follows a parcel-by-parcel iterative process similar to the CERCLA cleanup program; i.e., investigation followed by identification of cleanup options, culminating in the approval by the RWQCB of a "corrective action plan" (CAP) for each parcel (if necessary) and implementation of the cleanup actions identified in that plan.

In addition to the parcel-by-parcel reports described above, the Navy has conducted several basewide investigation and remediation programs for specific types of hazardous materials. Radiological investigations have been prepared on a basewide level for all parcels where there was a potential for radioactive contamination to be present. Basewide studies have also been performed for certain materials such as PCBs and asbestos-containing materials in buildings and structures, along with comprehensive evaluations of potentially contaminated steam lines, sewer, and storm drainage systems. These studies are described after the subsections describing the status of each parcel.

[285] Engineering /Remediation Resources Group, Inc., *Draft Feasibility Study Report for Parcel E,* July 2009; Engineering/Remediation Resources Group, *Draft Final Revised Remedial Investigation Feasibility Study Report for Parcel E-2,* February 1, 2009. These reports are on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

Current Conditions at HPS Parcel A

Parcel A consists of 75 acres, primarily on Hunters Point Hill and was formerly the residential area for the Shipyard. Parcel A contained 74 buildings, and the majority of the structures were former residences. Other buildings included storage, residential accessory structures, and administrative offices. Environmental investigations determined that site conditions posed no threat to human health or the environment. A No Further Action ROD was issued for Parcel A in 1995. Parcel A was deleted from the Superfund list in 1999. In December 2004, a Finding of Suitability to Transfer (FOST) for Parcel A was finalized, resulting in the transfer of Parcel A to the City.[286] The FOST for Parcel A described in detail the potential impact on future residents of Parcel A from the hazardous material release sites where remediation had not been completed on other adjacent parcels, particularly what is now Parcel E-2, and concluded that there would not be significant impacts on Parcel A from Parcel E-2 or other adjacent parcels at HPS.

Development underway on Parcel A is referred to as Phase I. Areas of Parcel A are within HPS Phase II, including portions of HPS Village Center and HPS South Districts.[287]

Current Conditions at HPS Parcel B

HPS Parcel B: Historic Uses

Parcel B was formerly part of the industrial support area and was used for fuel distribution, sandblasting, painting, machining, acid mixing, and metal fabrication, shipping, training, barracks, and offices. Other significant activities at Parcel B included potential disposal of decontamination materials from ships used during nuclear weapons testing in 1946 and 1947. Fill containing a high percentage of construction debris was placed on the northwestern side of Parcel B (an area known as IR Sites 7/18) during the expansion of the shipyard in the 1950s. In 1976, the Navy leased most of HPS, including all of the area now known as Parcel B, to Triple A. From 1945 through 1987, contaminant releases occurred during site operation under the Navy and Triple A; however, specific dates of releases are not known. Since 1986, portions of Parcel B have been leased for such uses as artists' studios, storage, and cabinet making. The 2008 Finding of Suitability to Lease (FOSL) provided for such uses.[288]

As reported in environmental investigation documents (refer to discussion below), about 75 to 80 percent of HPS ground surface is covered by pavement and buildings. There is no permanent surface water on Parcel B. Surface water runoff flows to the Bay via gravel-lined swales and/or percolates through surface soil during storm events. Groundwater at Parcel B consists of the A-Aquifer and the B-Aquifer, which are both shallow.

---

[286] US Department of the Navy Base Realignment and Closure Program Management Office West, Finding of Suitability to Transfer for Parcel A (Revision 3) Final, Hunters Point Shipyard, San Francisco, California, October 14, 2004. This document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

[287] Environmental requirements that ensure that the development of Parcel A is conducted in a manner that protects public health and safety have been, and will continue to be, guided by deed restrictions and the provisions of Article 31 of the San Francisco Municipal Code and associated plans. The deeds contain certain notice requirements related to motor oil in groundwater, asbestos building materials, and lead paint. Article 31 requires the Project Applicant to prepare dust control, off-site soil disposal, stormwater and erosion control plans and submit them to SFDPH for approval.

[288] The 2008 FOSL for Parcel B also included one building (Building 606) within Parcel D-1.

The A-Aquifer is not a source of drinking water. The B-Aquifer has never been used as a source of drinking water and has limited beneficial use. There is an extensive groundwater monitoring well network.

Parcel B: Results of Environmental Investigations

The primary chemicals in Parcel B soils at concentrations above cleanup goals are VOCs, semi-volatile organic compound (SVOCs),[289] PCBs, and metals. VOCs, chromium VI (hexavalent chromium), and mercury are the primary chemicals that have been detected in groundwater. The VOC plume has been the subject of a zero-valent iron (ZVI) injection treatability study and has been monitored for several years. Concentrations within the plume are decreasing as the result of ZVI injection during treatability study testing. Petroleum hydrocarbons have also been detected in Parcel B soil and groundwater. A survey in IR Sites 7/18 found methane present at concentrations that could potentially be explosive if vapors were to accumulate above levels of concern in a structure. The presence of methane may have been related to the construction debris placed there in the 1950s or a function of organic-rich Bay margin sediments, or a combination thereof.[290]

The original HHRA for Parcel B was conducted in 1996, followed by updates in 2003 and 2007 that accounted for ongoing cleanup and additional data gathering and evaluation. The 2007 assessment evaluated exposure scenarios for the individual metals and organic compounds that could present a risk for construction worker, residential, industrial, and recreational land uses. The assessment conservatively assumed these individuals could come into direct contact with soil, ingest it, or inhale dust containing the contaminants. Potential risks from groundwater are based primarily on breathing VOC vapors in indoor air that have migrated from groundwater in the A-aquifer.

The results of a screening-level ecological risk assessment (SLERA) identified potential unacceptable risk to benthic invertebrates, birds, and mammals from exposure to several metals (chromium VI, copper, lead, and mercury), pesticides, and PCBs in sediment along the shoreline.[291]

HPS Parcel B: Cleanup Status

The Navy has been performing basewide removal actions of radiological contamination to substantially eliminate identified pathways of exposure to radioactive contamination for surrounding populations and nearby ecosystems, such as nearby wetlands and the Bay. At Parcel B, the radiological cleanup activities have targeted radiologically impacted buildings, storm drains, and sanitary sewers. All waste material was

---

[289] A semi-volatile organic compound (SVOC) is an organic chemical that readily, but only partially, evaporates or changes from a liquid to gas at temperatures normally found at the ground surface and at shallow depths.

[291] ChaduxTt and Tetra Tech, *Parcel B Technical Memorandum in Support of a Record of Decision Amendment*, Final, December 12, 2007; ChaduxTt and Tetra Tech, Amended *Parcel B Record of Decision Amendment*, January 14, 2009; Jonas and Associates, *Final Second Five-Year Review of Remedial Actions Hunters Point Shipyard*, November 11, 2008. This document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

disposed at an appropriate off-site facility. In addition, the source of methane in IR Sites 7/18 has been remediated through excavation and groundwater monitoring, and documentation is pending.

In 1997, the Navy selected a remedial action for Parcel B, which was documented in a ROD. After performing detailed technical assessments over the last 10 years, including additional investigations, and a revised risk assessment, the Navy developed a proposed revised remedy. The revised approach takes into account updated information and includes items such as the ubiquitous nature of metals in soil across Parcel B as a function of the imported fill, the presence of methane and mercury, the findings of a SLERA, and findings from removal actions to address radiological contaminants.

The revised remedy was documented in a ROD Amendment, finalized in February 2009.[292] The ROD Amendment describes the reasons why the Navy selected the preferred alternative for cleaning up the soil and groundwater at Parcel B.[293] Some components of the revised remedy have been completed, such as the methane and mercury source removals. Other components are in progress, such as the radiological source removals (including radiologically impacted sewer and storm drain lines).[294]

The major components of the soil remedial actions are: excavating contaminated soil with off-site disposal, and covering with clean soil or other impervious surfaces such as pavement, concrete, or buildings; installing a soil vapor extraction system (SVE) to remove VOCs from soil and a soil vapor sampling program to evaluate the potential for vapor intrusion into buildings; constructing a shoreline revetment to protect ecological receptors along the Bay shoreline and to prevent or minimize wave-generated erosion from breaching the cover or cap; continuing the removal of radiologically contaminated building materials and soils; and implementation of Institutional Controls (ICs) to limit exposure to contaminated soil and groundwater by restricting specified land uses and activities on the parcel.[295] Figure III.K-2 (Parcel B Areas Requiring Institutional Controls) illustrates the Parcel B ICs.

The primary components of the groundwater cleanup consist of injecting a biological substrate to destroy VOCs in groundwater and monitoring, and water quality monitoring in the area of the mercury and methane source removals to evaluate the effectiveness of the removals in remediating mercury and methane in groundwater. ICs, such as prohibitions on the use of groundwater, would also be implemented.[296]

FIGURE III.K-2

Candlestick Point — Hunters Point Shipyard Phase II EIR

PARCEL B AREAS REQUIRING INSTITUTIONAL CONTROLS

Radiological contamination in soil will be remediated through ongoing removal and off-site disposal of impacted storm drain and sewer lines and related affected soil, and through removal of contaminated materials at IR Sites 7/18 (if found to be present) to a specific depth. A demarcation layer will be installed across areas of IR 7/18 to mark the boundary between the existing surface and a new soil cap. All buildings, former building sites, and excavated areas across Parcel B would be surveyed after cleanup is completed to ensure no residual radioactivity above the remediation goals is present. Additionally, groundwater monitoring will be conducted at IR Sites 7/18 to confirm that radionuclides have not been released into groundwater. Finally, ICs would be implemented to minimize inadvertent contact with potentially radiologically impacted media. The ICs for radiological impacts would only be applicable to IR Sites 7/18, and potentially for an area deep beneath Building 140, where a culvert is located that may contain radioactive material. The other potentially radiologically impacted sites would be cleared for unrestricted radiological release (or free release) as decided by California Department of Public Health (CDPH). If buildings are found to contain radiologically impacted materials, the Navy will decommission (i.e., remediate radiologically impacted materials) and/or demolish that building.

A CAP was prepared to address petroleum releases at Parcel B.[297] A Work Plan to implement the Parcel B CAP has also been prepared.[298] The remediation of total petroleum hydrocarbons-impacted areas is being conducted primarily under the oversight of RWQCB. These activities are anticipated to be completed in early 2010.

In the above description of the remedy for Parcel B, the terms "cover" and "cap" are both used. Although these terms are sometimes used interchangeably in other contexts, in this EIR they refer to two similar, but distinct, types of remedies that are both designed to prevent exposure from known or suspected residual contaminants (also referred to as cutting off an exposure pathway).

The term "cover" as used in this EIR refers to a remedy requiring that the surface covers being installed (or remaining in place) to support the development (e.g., building slabs, pavement for roads, concrete for sidewalks, soil or grass for landscaped areas), meet certain specifications of thickness and be maintained to prevent breaches. The ICs imposed in conjunction with cover remedies generally contemplate that development activities will result in temporary breaches of the cover and allow such temporary breaches with the approval of the regulatory agency.

The term "cap" as used in this EIR refers to a remedy requiring the installation of a surface specifically engineered to be placed on top of an area of known or suspected residual contamination (typically a landfill); the surface may be asphalt, concrete, or soil, but is generally more robust than a "cover" remedy, includes a "demarcation layer" of some sort, is often accompanied with methane recovery or monitoring equipment, and more intensive operation and maintenance requirements than a "cover" remedy. The ICs imposed in conjunction with cap remedies generally make it more difficult to secure approval for a breach of the cap than the ICs for a cover remedy.

In the context of the Parcel B ROD, the soil remedy for IR sites 7/18 is referred to as a "cap," and the soil remedy for the remainder of the parcel is referred to as a "cover."

[297] Shaw Environmental, *Final Petroleum Hydrocarbon Corrective Action Plan, Parcel B, Revision 2008*, June 25, 2008.
[298] Innovative Technical Solutions, *Draft Project Work Plant, Petroleum Hydrocarbon Corrective Action, Parcel B,* March 2009.

The implementation and enforcement of ICs at Parcel B and other parcels is described in more detail under Section III.K.3 (Regulatory Framework).

Current Conditions at HPS Parcels C and UC-2

Parcels C and UC-2: Historic Uses

Parcel C is 76 acres of shoreline and lowland along the east-central portion of HPS. It is the oldest portion of the shipyard and has been used primarily for industrial operations since the late 1800s. Within the boundaries of Parcel C are 35 buildings, two drydocks, one wharf, nine ship berths, and one pier. Soil at Parcel C consists largely of artificial fill. As reported in the RI, asphalt, concrete, or buildings cover approximately 90 percent of the surface soil. Bedrock is in close to the surface in areas within Parcel C; hence its desirability for the construction of a drydock within competent material.

HPS Parcels C and UC-2: Results of Environmental Investigations

The primary chemical contaminants detected in Parcel C soil and groundwater include VOCs, SVOCs, PCBs, petroleum hydrocarbons (gasoline and diesel), and metals. Identified sources of these chemicals included leaking sumps containing VOCs and SVOCs, leaking fuel (gasoline and diesel) lines and USTs, sandblast material containing lead and other metals, and leaking PCB-containing transformers. Petroleum hydrocarbon and VOC plumes in groundwater occur in the eastern half and west-central portions of Parcel C. Ongoing quarterly groundwater monitoring indicates exceedances of water quality criteria by certain metals and VOCs. The current magnitude and extent of these chemicals in groundwater at Parcel C are generally consistent with previous quarters, with the exception of an increase recently of vinyl chloride levels in one monitoring well. The Parcel C HHRA indicates that there are areas that require remediation to meet acceptable risk levels for the future land uses as defined in the 1997 Agency Re-Use Plan.[299]

There is not a significant risk to terrestrial species because of the lack of ecological receptors at the site under current use; however, petroleum hydrocarbons in soil and groundwater pose a risk to aquatic receptors in the Bay.[300]

HPS Parcels C and UC-2: Cleanup Status

Numerous physical cleanup activities have been implemented at Parcels C and UC-2, including: removal of USTs and subsurface fuel lines; excavation and/or encapsulation of soil; collection and removal of sandblast waste; encapsulation of Drydock 4 waste drainage culverts by sealing all inlets and outlets to the culverts with concrete slurry, thereby, eliminating the pathways of exposure of ecological receptors to hazardous substances. In addition, groundwater treatability studies have been performed for VOCs, along with in-situ bioremediation, which have demonstrated reductions in VOC concentrations in soil and groundwater.[301] The Navy published a FS in 2008 as an update to the 1998 FS.[302] Nine remediation alternatives were identified in the FS, with the highest-rated alternative comprising a combination of soil excavation and off-site disposal, covers, soil vapor extraction for VOCs, in-situ groundwater treatment,

and ICs. A draft PP outlining the Navy's preferred remedies was published in January 2009. A draft ROD identifying the selected remedy is expected to be issued in December 2009. The final ROD is expected to be signed in the winter of 2010.[303]

Current Conditions at HPS Parcel D (including newly created Parcels D-1, D-2, G, and UC-1)

HPS Parcel D: Historic Uses

The original Parcel D consisted of 101 acres of the southeast-central portion of HPS. Most of the land at Parcel D was formerly part of the industrial support area and was used for shipping, ship repair, and office and commercial activities. The docks at Parcel D were formerly part of the industrial production area. Segments of the basewide steam and sanitary sewer/storm drain system traverse the parcel. Portions of Parcel D were also used by the NRDL. As reported in the RI, approximately 85 percent of the ground surface in Parcel D is covered by pavement and buildings.

HPS Parcel D (Including D-1, D-2, G, and UC-1): Results of Investigations

The primary chemical contaminants detected in Parcel D soil include PCBs and petroleum hydrocarbons (diesel and motor oil), and metals. Diesel and motor oil were also detected in groundwater. Elevated concentrations of lead in soil were detected in several areas. Arsenic and beryllium were detected in both soil and groundwater. Other metals found in serpentinite-derived fill materials, such as arsenic, chromium, nickel, and manganese, were also detected throughout the parcel in soil and/or groundwater. Chromium VI (hexavalent chromium) was detected within groundwater below IR-09, the former pickling and plating yard. Cesium-137 and associated elements strontium and europium were detected on asphalt adjacent to the secondary containment vault behind Buildings 364 and 365. Groundwater monitoring has been conducted on a semi-annual basis across Parcel D. Based on data collected as part of the Groundwater Treatability Study in 2008, the primary chemicals of concern continue to be metals and VOCs. However, VOC concentrations have decreased, and VOC and hexavalent and total chromium concentrations continue to decline as a result of the in-situ treatment (conducted as part of the treatability study, as discussed in more detail below).

Metals (arsenic, lead, manganese) and a few VOCs are the primary contaminants in soil requiring the need for remediation. The following chemical contaminants in groundwater are associated with potential exposure to A-aquifer groundwater via vapor intrusion: benzene, carbon tetrachloride, chloroform, naphthalene, tetrachlorethene, trichloroethene, xylene, and methylene chloride. The completed ecological risk evaluations concluded potential exposure pathways (dermal contact and ingestion of contaminated soil) did not pose a significant risk because of the lack of ecological receptors at the site.[304]

---

[303] California Department of Toxic Substances Control EnviroStor website: Hunters Point Naval Shipyard Parcel C. http://www.envirostor.dtsc.ca.gov/public/profile_report.asp?global_ id=38440003.

[304] SulTech, *Final Revised Feasibility Study for Parcel D Hunters Point Shipyard, San Francisco*, November 30, 2007; Jonas and Associates, *Final Second Five-Year Review of Remedial Actions Hunters Point Shipyard*, November 11, 2008. These documents are on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

HPS Parcel D (Including D-1, D-2, G, and UC-1): Cleanup Status

Several remediation activities have been implemented at Parcel D: removal of PCB-contaminated soil; removal of USTs and associated pipelines; collection and removal of sandblast waste; excavation of radiologically contaminated soil; and removal of contaminated sediment from storm drain lines.

The Navy revised the Parcel D FS in 2007, and prepared a draft PP for Parcel D that presented a proposal for remedial action to be selected in the ROD for Parcel D. It includes all of Parcel D, but for remedy selection, Parcel D was divided into four new parcels: Parcels D-l, D-2, G, and UC-l. Three RODs were prepared: one combined ROD for Parcels D-1 and UC-l and one each for Parcel D-2 and Parcel G. The Navy issued a ROD for Parcel G in February 2009[305] and a ROD for D-1 and UC-1 in July 2009.[306] In the fall of 2009 the Navy is planning to finalize a No Action ROD for Parcel D-2.[307]

The Navy is proposing the following actions in Parcels D-1, G, and UC-1: excavation and off-site disposal of contaminated soils and installing soil covers; treating groundwater at specific locations by injecting chemicals or biological nutrients to break down the chemicals, along with groundwater monitoring; continuing the removal of radiologically contaminated building materials and soils.[308] Similar to Parcel B, ICs will be used to implement land use restrictions to limit potential exposure of future landowner(s) and user(s) to hazardous substances present in Parcels D-1, G, and UC-1, and to ensure the integrity of the remedial actions (refer to Figure III.K-3 [Parcels D and G Areas Requiring Institutional Controls]).

Current Conditions at HPS Parcels E and E-2

HPS Parcels E and E-2: Historic Uses

In September 2004, the Navy divided the original Parcel E into two parcels: Parcel E and Parcel E-2. Parcel E consists of 138 acres of shoreline and lowland area in the southern portion of HPS. Nearly all of the Parcel E land area was created using artificial fill. Most of Parcel E is covered by annual grasses; the rest is covered by asphalt, buildings, or other structures used in light-industrial operations related to ship repair. Historically, Parcel E was a mixed-use and industrial area that supported HPS shipping and ship repair activities. Areas near the shoreline were used to store construction and industrial materials and to dispose of industrial waste and construction debris. Portions of Parcel E were also used for office and laboratory space by the NRDL.

PBS&J 10.30.09 08068 | JCS | 09

FIGURE III.K-3

Candlestick Point — Hunters Point Shipyard Phase II EIR

PARCELS D AND G AREAS REQUIRING INSTITUTIONAL CONTROLS

Parcel E-2 consists of 47.4 acres of shoreline and lowland areas along the southwestern portion of HPS Phase II and is part of an area created from the 1940s to the 1960s by filling in the Bay margin with a variety of material, including soil, crushed bedrock, dredged sediments, and debris. From 1958 to 1974, the landfill received liquid chemical waste, asbestos, domestic wastes and refuse, dredge spoil materials, sandblast grit, solvent wastes, and low-level radioactive wastes from shipboard radium dials, including electronic equipment.

HPS Parcels E and E-2: Results of Investigations

The chemicals of concern at Parcel E include metals and organic chemicals such as VOCs, PAHs, PCBs, and pesticides. The chemicals of concern at Parcel E-2 include metals, PCBs, SVOCs, pesticides, and petroleum hydrocarbons. The radionuclides of concern associated with Parcel E-2 include cobalt-60, cesium-137, radium-226, and strontium-90.

The HHRA results for groundwater indicated that the risk from potential exposure to VOCs (such as chlorinated solvents and benzene) in the A-aquifer via vapor intrusion exceeded action levels at certain locations. The risk assessment also evaluated potential risks from exposure to chemicals in the B-aquifer from domestic use. The chemicals driving risk in B-aquifer groundwater are metals and VOCs. Potential human health risk from exposure to chemicals present in sediment was also evaluated for the shoreline at HPS. Based on this evaluation, hexavalent chromium (chromium VI), total chromium, and PCBs appear to be the primary chemicals of concern for the evaluation of human health in sediment along the Parcel E shoreline.

Two ecological risk assessments were performed for Parcel E: (1) the baseline ecological risk assessment (BERA), prepared in 1997, which evaluated risks from exposure to soil in areas planned for open space reuse along the Parcel E shoreline; and (2) a screening level ecological risk assessment (SLERA), prepared in 2005, which evaluated risks from exposure to sediment in the intertidal zone along the Parcel E-2 shoreline. The BERA found potential risk to birds and mammals from exposure to copper, lead, and total PCBs in soil along the shoreline. The SLERA found potential risk to benthic invertebrates, birds, and mammals from exposure to metals and total PCBs in surface and subsurface sediments along the shoreline.[309] Although the SLERA was characterized as an assessment of Parcels E/E-2, these sediments posing risk to ecological receptors are actually part of the Parcel F submerged lands because the boundary between Parcels E and E-2 is defined in a manner that makes all sediments part of Parcel F.

HPS Parcels E and E-2: Cleanup Status

Numerous physical cleanup activities have been implemented at Parcels E and E-2. These include: collection and removal of 5,000 tons of sandblast waste; removal and containment of floating petroleum product to prevent further migration to the Bay; a SVE system to extract VOCs from the subsurface; excavation and removal of soil contaminated with PCBs, removal and/or containment of radioactive

[309] Barajas and Associates, *Final Revised Remedial Investigation Report for Parcel E Hunters Point Shipyard*, May 2, 2008; Jonas and Associates, *Final Second Five-Year Review of Remedial Actions Hunters Point Shipyard*, November 11, 2008; Engineering/Remediation Resources Group, *Draft Final Remedial Investigation /Feasibility Study Report for Parcel E-2, February 1, 2009*. These documents are on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

constituents; and petroleum compounds; removal of contaminated soil and placement of a clean soil cap in the metal debris reef and metal slag areas.

In Parcel E-2, the Navy has installed a groundwater containment and extraction system at the southeast portion of the landfill to reduce the potential for release of chemical constituents into the Bay. This system includes sheet piling and a groundwater extraction system to control potential mounding of shallow groundwater at the southern end of the landfill. A multi-layer interim cap was constructed on a portion of the Parcel E-2 Landfill to prevent oxygen intrusion and extinguish smoldering subsurface areas following a subsurface fire that burned for several months in 2000. Following characterization of the nature and extent of landfill gas, a landfill gas barrier and monitoring system was constructed at the northern end of the landfill to prevent methane gas migration from reaching the University of California San Francisco (UCSF) facility adjacent to parcel E-2 (the UCSF facility is outside of HPS Phase II). In addition, ongoing monitoring programs at Parcel E-2 include Storm Water Discharge Management Program; Landfill Cover Inspection and Maintenance Program; Basewide Groundwater Monitoring Program; and Landfill Gas Control and Monitoring Program.[310,311]

Before the PPs and RODs can be completed for Parcels E and E-2, a methane gas survey must be completed at Parcel E-2, and a groundwater treatability study is planned for Parcel E-2.[312] In addition, the HHRA has been revised, and an updated draft Parcel E FS was prepared. For Parcel E-2, the range of cleanup options includes: excavation and off-site disposal of solid waste, soil, and sediment (including monitoring and institutional controls); or on-site containment of solid waste, soil, and sediment with Hot Spot Removal (including monitoring and institutional controls or some combination thereof). [313]

The draft PPs and RODs for E and E-2 are expected in the 2010–2011 timeframe. Remedial design plans and completion reports will be developed and are anticipated in the 2012–2014 timeframe.[314]

Current Conditions at HPS Parcel F

HPS Parcel F: Historic Uses

Parcel F comprises 446 acres of underwater property[315] surrounding all portions of HPS to the north, east, south, and southwest. Figure III.K-4 (Hunters Point Shipyard Phase II Parcel F Subareas) shows Parcel F in relation to the other parcels and five specific investigation subareas within the parcel. Features of Parcel F include pier, slip, and drydock areas and offshore sediment. As noted for Parcel E/E-2, the sediments are included as part of the Parcel F submerged lands because the boundary between Parcels E and E-2 is defined in a manner that makes all sediments part of Parcel F.

HPS Parcel F: Results of Environmental Investigations

Numerous investigations have been conducted at Parcel F. The investigations include an RI/FS, a human health risk assessment, and an updated FS, as well as the collection of surface and subsurface sediment samples for chemical and ecological toxicity evaluations. Fish and invertebrate tissue samples also were collected at Parcel F and analyzed for chemicals. During Phase 1A and Phase 1B Ecological Risk Assessments, Parcel F was subdivided into eleven subareas. Based on the previous investigation results, five areas were identified for further evaluation: Area I (India Basin Subarea), Area III (Point Avisadero Subarea), Area VIII (Eastern Wetland Subarea), Area IX (Oil Reclamation Subarea), and Area X (South Basin Subarea), which are shown in Figure III.K-4. Although no final determination has been made, at this time no further evaluation of the sediment is considered to be necessary for the remaining subareas.

The India Basin Subarea I of Parcel F is north of Drydocks 5, 6, and 7. Subarea III (Point Avisadero) is between Pier C and Drydock 3. Subareas VIII, IX, and X (Eastern Wetland, Oil Reclamation, and South Basin, respectively) adjoin Parcels E and E-2 on the west side of HPS Phase II. The location for the proposed marina is within Parcel F, but it is not within one of the subareas for which further evaluation has been recommended.

The results of a shoreline investigation in 2002 evaluated whether contamination in Parcels E and E-2 had the potential to migrate (or had migrated) to sediments in the adjacent offshore area of Parcel F, or to affect benthic invertebrates, birds, and mammals in the shoreline area. In Subarea III, copper and mercury were identified as the primary risk drivers; PCBs were of greatest concern in Subareas IX and X. These chemicals also exceeded concentrations considered safe for benthic invertebrates directly exposed to sediment. PCBs also were shown to cause potential risk to humans if they were to consume shellfish collected at HPS. Although the issue of concentration of chemicals in fish is regional, the study also evaluated whether differences existed between levels of chemicals in fish from the vicinity of HPS and those collected elsewhere in the Bay. Results of statistical comparisons of fish tissue data at HPS indicated

HUNTERS POINT SHIPYARD PHASE II PARCEL F SUBAREAS

FIGURE III.K-4

the results were statistically similar to regional levels.[316] No unacceptable ecological risk was indicated by sediments in Subareas I (India Basin) or VIII (Eastern Wetland).

HPS Parcel F: Cleanup Status

The Navy has implemented source control measures to help reduce contaminant levels including: extensive removal of contaminated soil, and sediment and debris along the Parcels B, E, and E-2 shorelines; storm drain cleaning program; and installation of a steel sheet-pile wall on the Bay side of the former industrial landfill located in Parcel E-2. A revised Parcel F FS has identified a range of alternatives to remediate Parcel F, the offshore areas of the Shipyard. For Subarea III, the options include removal/backfill and off-site disposal of affected media in combination with a cap and institutional controls. For Subareas IX/X, similar methods could be used, along with in-situ stabilization and natural recovery with monitoring. (For Subareas I and VIII, no remedial actions were recommended by the Navy as being necessary because no unacceptable ecological risk was identified.) The Navy will select the preferred remedial alternative after receipt and resolution of regulatory agency comments. The Navy will present its preferred alternative to the public in a PP.[317] The draft PP and ROD are anticipated to be issued in 2012 or 2013.[318]

Basewide Environmental Investigations at HPS

Basewide Historical Radiological Assessment

HPS has been the subject of many radiological investigations, with particular focus on ionizing radiation. In 2000, the Navy began preparing a basewide assessment of the *potential* for radiological contamination in the buildings and environmental media. The preparation of the Historical Radiological Assessment 1939-2003 (HRA) was an extended process that involved review of thousands of records from 14 federal and private records repositories, electronic mail, and telephone contact with 200 persons with potential knowledge of radiological operations at HPS.

The primary purpose of the HRA was to designate sites as "impacted" or "non-impacted." As identified in the HRA, an impacted site was one that had the potential for radioactive contamination based on historical information, or was known to contain or have contained radioactive contamination. Designation as "impacted" did not confirm that radioactive contamination was present; only that the possibility existed and

318 California Department of Toxic Substances Control EnviroStor website: Hunters Point Naval Shipyard Parcel F. http://www.envirostor.dtsc.ca.gov/public/profile_report (accessed July 2009).

needed to be investigated. Non-impacted sites are those with no history of radiological operations or those that have no reasonable potential for residual contamination (such as residential or administrative buildings).

Of the 882 HPS historical and current sites and support areas identified in the HRA, 91 were identified as "impacted." The impacted sites included: buildings; drydocks; former building sites; outdoor areas; IR sites, ships' berths; the Gun Mole Pier (re-gunning pier); and septic, sanitary, and storm drain systems. Of the 91 sites, 29 were recommended for review of the Final Status Survey; these sites can be recommended for free release only when the Navy and appropriate regulatory agencies have reviewed the Final Status Survey report and agreed with the assessment. Sixty impacted sites were recommended for further investigative actions or remediation. The HRA identified the following potentially contaminated media: surface soils, subsurface soil and media, structures and drainage systems. The assessment concluded, however, that there was no concern for airborne contamination from the potentially contaminated media in their undisturbed state, and no defined impacted site was recommended for emergency action. Eleven impacted sites required restricted access until the completion of remedial activities as a result of the presence of known levels of undisturbed radioactive contamination.

The overall conclusion of the HRA was that although low levels of radioactive contamination exist at HPS, no imminent threat or substantial risk exists to tenants, the environment of HPS, or the local community.[319] This conclusion has been reinforced by subsequent Finding of Suitability for Lease (FOSL)[320] issued by the Navy for areas in Parcel B and Building 606 in Parcel D and approved by the regulatory agencies authorizing leases for various uses involving hundreds of employees, artists, and visitors in close proximity to various "impacted" sites each day. A Basewide Radiological Work Plan was subsequently prepared, describing survey and decontamination approaches to be implemented in support of radiological release of buildings and areas.[321]

Other Basewide Investigations for Specific Contaminants at HPS

In addition to the radiological investigations and cleanups, other Navy efforts include basewide investigation and remediation for PCBs, asbestos containing building materials (ACBM), underground and aboveground storage tanks (ASTs). Transformers containing PCBs have been removed, but investigation of soils for PCB contamination has been addressed separately for each parcel. The Navy has conducted building surveys for asbestos and has removed some hazardous ACBM in all parcels except the Parcel F submerged lands where there are no buildings. The Navy investigated USTs and removed or closed them in place in two phases in the 1990s. Most of the USTs contained petroleum products, waste oils, or solvents. The Navy also has removed numerous ASTs. Most of the ASTs contained petroleum products or water, except for two that contained solvents. For both USTs and ASTs, associated contaminated soils

have been removed and disposed of off site.[322] As part of the implementation of the remedies set forth in each Parcel's ROD and petroleum Corrective Action Plan, all releases associated with ASTs or USTs will be addressed and determined by the FFA Signatories to be safe for the intended use.

Hazardous Building Materials: Current Conditions

Hazardous building materials include asbestos-containing building materials, electrical equipment such as transformers and fluorescent light ballasts that may contain PCBs, fluorescent lights and switches containing mercury, and lead-based paints. Until the 1970s, asbestos was commonly used in building materials, including use in insulation materials, shingles and siding, roofing felt, floor tiles, brake linings, and acoustical ceiling material. Asbestos is a known carcinogen and presents a public health hazard if it is present in friable (easily crumbled) form. PCBs were commonly manufactured and used in the United States between 1929 and 1977 for use in devices such as electrical transformers and capacitors and fluorescent light ballasts. Spent fluorescent light tubes commonly contain mercury vapors at levels high enough to be considered a hazardous waste under California law; depending on the levels of mercury present, the light tubes may also be classified as hazardous under federal law. Lead-based paint was commonly used prior to 1960 and is likely present in buildings constructed prior to 1960. The Department of Defense assumes that any military building constructed or rehabilitated prior to 1978 contains lead-based paint. Lead is toxic to humans, particularly young children, and can cause a range of human health effects depending on the level of exposure.

The investigation of some hazardous materials in buildings and structures in HPS Phase II has been completed by the Navy for parcels within the site. As described previously, damaged or friable asbestos and PCBs have been removed. However, lead-based paint surveys have not been completed for structures in Parcels B, C, D/G, and E.

Project-wide Current Conditions

This section describes Project-wide hazards and hazardous materials conditions such as naturally occurring asbestos, conditions at off-site locations, hazardous materials use on the Project site, and proximity to schools.

Naturally Occurring Asbestos

Asbestos is a naturally occurring mineral found in serpentinite rocks. As shown in Figure III.L-1 (Geologic Map) of Section III.L, there is an area of serpentinite mapped in the northern part of HPS Phase II, which extends north into the India Basin area. Serpentinite may also underlie proposed roadway segment locations in these areas. Previously disturbed serpentinite fragments have also been identified in fill material at HPS Phase II.

Rock types within Candlestick Point are predominantly Franciscan chert, slope debris, ravine fill, and undifferentiated sedimentary deposits. There is no mapped serpentinite within the boundaries of Candlestick Point or locations to the west where proposed roadway improvements could be constructed.

[322] Hunters Point Shipyard Reuse Final EIR, June 2000, pp.3-111 to 3-114. This document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

Off-Site Hazardous Materials Release Sites

One site northeast of HPS Phase II is listed on the EnviroStor database and has been the subject of ongoing investigation for contaminated groundwater. The Bayview Plume Study Area is bounded on the west by Keith Street, on the north by Quesada Avenue, on the east by Griffith Street, and on the south by Shafter Avenue. Groundwater is affected with a dry-cleaning solvent (PCE), but results of remedial investigations show that the direction of groundwater flow is towards the northwest, away from the Project site.[323]

Conditions at Off-Site Improvement Locations

The Site History/Initial Site Assessment technical report prepared for the Bayview Transportation Improvements Project (currently under environmental review) reviewed environmental conditions at most of the locations where the off-site improvements (e.g., roadways) may involve disturbance of soil or the existing asphalt cover.[324] At Griffith Street, Ingalls Street, and Carroll Avenue, the report concluded that historic and current land uses indicate the potential for hazardous substances to have been released at some locations, indicating the potential presence of hazardous materials in soil and groundwater in these areas. The proposed segment along Palou Avenue was not included in the Site History/Initial Site Assessment technical report prepared for the Bayview Transportation Improvements Project (currently under environemental review), however, so conditions are not known.

Previous investigations that identified historic uses, USTs, and sampling results along the alignments, along with a review of agency databases, show that many of the locations identified in the above-referenced Site History/Initial Site Assessment report have received regulatory closure.[325] However, some sites may still require investigation or remediation, and there may be new sites that have not been comprehensively evaluated for the presence of hazardous materials contamination in soil at the specific locations where soil disturbance could occur.

Hazardous Materials Use and Hazardous Waste

Section III.B. (Land Use and Plans) describes the current land uses within the Project site. There are no industrial, manufacturing/processing, or similar large-scale businesses that routinely use, store, or transport substantial quantities of hazardous materials in the Project site. Limited quantities of household-type products containing hazardous materials such as cleaning agents, paints/solvents, and pesticides are associated with residential uses in Alice Griffith Public Housing and Candlestick Park Stadium operations.

Several former Navy buildings within HPS Phase II are leased to artists and woodworking and picture framing businesses. Some art materials and items used in woodworking contain hazardous materials, but the quantities on site are minimal. As a condition of their leasing agreements, tenants are responsible for the management and

appropriate disposal of their hazardous materials and wastes. Tenants are required to comply with all applicable laws and regulations pertaining to the use, transport, storage, and disposal of these materials.

According to information compiled for the Bayview Hunters Point Redevelopment Plan EIR and a review of agency databases in 2009,[326] there is one business with a reported address within the Project site that generates hazardous waste and that is regulated by the USEPA. It is a "small quantity generator" as defined by the USEPA, meaning it generates from approximately 220 to 2,200 pounds of hazardous waste per month, and is required to report hazardous waste quantities in accordance with *Resource Conservation and Recovery Act* (RCRA) requirements.

Schools within One-Quarter Mile of the Project

There are two schools within one-quarter mile of some portions of the Project. The Bret Harte Elementary School at 1035 Gilman Street is within one-quarter mile of the Alice Griffith public housing development. Muhammad University of Islam, a year-round elementary school, is located adjacent to the Hillside portion of HPS Phase I development and is within one-quarter mile of the western-most portion of the Project boundary. Another school in the Project vicinity, Gloria R. Davis Academic Middle School (1195 Hudson Avenue), is more than one-quarter mile from the Project.

Regulatory Process for Cleanup Process at HPS Phase II

The oversight of hazardous materials release sites often involves several different agencies that may have overlapping authority and jurisdiction. The DTSC and RWQCB are the two primary state agencies responsible for issues pertaining to hazardous materials release sites.

This section describes regulatory issues that are unique to the cleanup at HPS Phase II and summarizes the primary regulations pertaining to the types of investigation, cleanup, and construction activities that would occur in the Project. This section also describes the general regulatory framework applicable to hazardous materials throughout the Project site.

The general regulatory framework governing cleanup at closed military bases on the NPL like HPS Phase II is described in Section III.K.2 (Setting). The two subsections below describe two specific aspects of the regulatory framework at closed military bases on the NPL: the legal relationship between the cleanup process and the transfer of property at a closed military base; and the establishment and enforcement of institutional controls. In addition, this section notes two considerations, outside the normal regulatory framework applicable to cleanup and redevelopment at contaminated closed military bases that are unique to HPS Phase II.

First, on November 7, 2000, the voters of San Francisco voted to approve Proposition P, which called upon the Navy to remediate HPS to the highest levels practical to ensure flexible reuse of the property. On July 30, 2001, the Board of Supervisors approved a resolution confirming as the policy of the City and

[326] California Department of Toxic Substances Control EnviroStor website. http://www.envirostor.dtsc.ca.gov/public (accessed July 2009). State Water Resources Control Board Geotracker. http://geotracker.swrcb.ca.gov/ (accessed July 2009).

County of San Francisco that the Hunters Point Naval Shipyard should be cleaned of toxic and hazardous pollution by the Navy to the highest practical level.

Second, on March 31, 2004, the San Francisco Redevelopment Agency (Agency) and the United States Navy entered into a Conveyance Agreement for Hunters Point Naval Shipyard (HPS Conveyance Agreement). Under the HPS Conveyance Agreement, one of the "closing conditions" for conveying a parcel at HPS from the Navy to the Agency is that the Navy obtain Regulator Assurances prior to conveyance. That term is defined in the Conveyance Agreement to mean written confirmation by the USEPA, DTSC, and the RWQCB that sufficient remedial action has been taken to protect human health and the environment for the parcel's intended future use.

Legal Relationship between the Cleanup Process and Property Transfer at Hunters Point Shipyard

CERCLA requires that, prior to real property conveyance, the Navy must remediate hazardous substances to a level consistent with the protection of human health and the environment; or, if conveying property before completion of remediation, the Navy must ensure that the property is suitable for conveyance for the use intended and that the intended use is consistent with the protection of human health and the environment. In other words, there are two ways in which the Navy can transfer title to the HPS property: (1) after complete remediation of a parcel (e.g., the approach taken with Parcel A) or (2) or as an early transfer before remediation is completed. In addition, the Navy can lease the property before remediation is complete. The conditions associated with title transfers or leases are summarized below.

Transfer After Completion of Cleanup at HPS

The first option for title transfer assumes that all remediation necessary to protect human health and the environment has been conducted on the property. In conveying property that is completely remediated, the Navy documents its findings in a Finding of Suitability to Transfer (FOST).

The FOST would document environmental findings regarding the proposed transfer. It would summarize the environmental condition of the property and, where appropriate, identify any environmental conditions that would pose constraints to activities or uses of the property. It would identify any environmental covenants, conditions, or restrictions that would be included in the deed to ensure protection of human health and the environment, taking into consideration the agreed-upon land uses. Under CERCLA, the deed must contain a notice of the type and quantity of and timeframe in which hazardous substances were stored, disposed, or released on the property and any remedial action taken. The deed must warrant that all remedial action necessary to protect human health and the environment with respect to any remaining hazardous substances has been taken before transfer. Additionally, the deed must warrant that any remedial action found necessary with respect to such hazardous substances after the transfer will be taken by the Navy. At the time of transfer, the Navy is required to covenant that all required remediation has been completed and that if additional remedial action is needed with respect to contaminants on the property at the time of transfer, further cleanup will be the Navy's responsibility. The HPS Conveyance Agreement also requires federal and state environmental regulator concurrence prior to conveyance of a parcel at HPS.

Neither CERCLA nor Department of Defense policy nor regulations require federal or state environmental regulators to concur in the Navy's Finding of Suitability for Transfer; however, as described above, the HPS Conveyance Agreement in essence requires such concurrence prior to conveyance of a parcel at HPS.

Transfer Before Completion of Cleanup (Early Transfer) at HPS Phase II

The second way the Navy can convey title to property at HPS Phase II is a process referred to as "early transfer." This means that title would transfer from the Navy to the Agency before all necessary remedial action has been completed, provided certain conditions specified in CERCLA have been met. These conditions include the following:

- Agreement by USEPA and the State that the property is suitable for the intended use of the property during the completion of the remediation activities, and that the intended use will be protective of human health and the environment;
- Public notice and comment;
- Property use restrictions, if necessary, to ensure that human health and the environment are protected and that the necessary remedial actions can take place; and
- Assurances from the federal government that conveyance of the property will not substantially delay response actions at the property and that the necessary response actions will be completed after conveyance.

The Navy would document its determination that the property may be transferred prior to the completion of all remediation in a Finding of Suitability for Early Transfer (FOSET). For an early transfer to proceed at an NPL site like HPS Phase II, the USEPA, with the concurrence of the Governor of the state of California, must authorize the early transfer. Under CERCLA, USEPA and the Governor may authorize an early transfer only if each determines that:

- The property is suitable for transfer for the use intended by the transferee;
- The intended use is consistent with protection of human health and the environment;
- The deed will contain restrictions necessary to ensure protection of human health and the environment; and
- All remedial investigations and response actions will be completed by the transferee notwithstanding the transfer of the property.

The Navy and Agency envision that some of the property at HPS Phase II will be allowed to transfer early. Current plans are for an early transfer of title to Parcels B (except for the area referred to as IR 7/18, discussed further below) and G, followed by potential early transfers of other parcels if deemed appropriate and necessary. Under the early transfers as currently envisioned at HPS Phase II, the Navy would complete all radiological cleanup activities and obtain an approved ROD for any given parcel prior to title transfer. Because the Navy has already conducted significant remedial activities, it is expected that the Navy may complete, before transfer, the initial installation of groundwater treatment systems and soil vapor extraction systems and conduct major soil excavations. Responsibility for any remedial work not yet completed at the time of transfer would be transferred from the Navy to the Agency under the terms of an Early Transfer Cooperative Agreement (ETCA). The ETCA would grant Navy funds to the Agency sufficient to complete the Navy's cleanup obligations.

It is anticipated that the Agency would then be responsible for those remedial activities that could be carried out most easily as part of the redevelopment of the property. Those remedial actions could include:

- Removal of limited areas of contaminated soil;
- Completion of previously-commenced groundwater remediation and groundwater monitoring;
- Construction of revetment walls in Parcel B along the shoreline to prevent contaminant migration into the Bay;
- Placement of vapor barriers under buildings where they are found to be necessary; and
- Placement of a final cover over existing soil through the use of new building foundations, roads, sidewalks, parking lots and/or placement of clean fill in open space areas.

Some or all of the Agency's remediation obligations under the ETCA may be assumed by the Project Applicant of the property, subject to a separate agreement. In addition to the ETCA, the Agency and the Project Applicant would be expected to enter into a legally enforceable remediation agreement with USEPA and state regulatory agencies called an Administrative Order on Consent (AOC). This document would commit the Agency and Project Applicant to completing the remedial work that it has agreed to undertake for the Navy. The AOC would be one of the documents supporting the decision by the Governor and USEPA Administrator to allow an early transfer under CERCLA. In turn, USEPA and the State would be expected to modify the terms of the FFA with the Navy to provide that the Navy is not responsible for the scope of work assumed by the Agency and Project Applicant, provided the Agency and Project Applicant continue to fulfill those obligations.

Leasing Property Before Completion of Cleanup at HPS Phase II

CERCLA also allows the Department of Defense to lease contaminated or potentially contaminated properties to third parties. Under this scenario, the Navy would prepare a Finding of Suitability to Lease (FOSL), and USEPA must determine that the property is suitable for lease for the uses contemplated, and that the uses are consistent with protection of human health and the environment and with remedial action that will be taken. The FOSL would document environmental findings for the parcels and the suitability of parcels for a lease. A lease could be a short-term lease (generally less than 10 years) or a long-term lease (e.g., 60 years) which envisions eventual conveyance of the property. This longer-term lease is called a Lease in Furtherance of Conveyance (LIFOC). The FOSL would include a summary of contamination and risk, and require lease notifications and restrictions necessary to protect against threats to human health and the environment to be included in the LIFOC, and include adequate assurances that all necessary remedial action has been taken or will be taken after the execution of the lease.

The Navy may lease some property to the Agency under a LIFOC, such as where it desires to give the Agency access to the property to carry out some specified activities but the property is not yet ready for a transfer under a FOST or FOSET. Activities likely to be conducted under a short-term lease or LIFOC include abatement of asbestos containing materials or lead-based paint and/or building demolition. (Abatement activities not involving building demolition may also be conducted pursuant to a license issued by the Navy). Interim uses of certain buildings or areas by commercial or industrial subtenants might also take place under a short-term lease or LIFOC. The FOSL would be expected to require the terms of the lease to contain certain restrictions on activities and uses, such as a prohibition against soil excavation without approval of a workplan by the Navy and USEPA.

Under the any leasing scenario, responsibility for environmental remediation at leased property would not transfer to the Agency or Project Applicant as is expected at early-transferred property. Instead, the Navy would continue to be responsible for environmental remediation during the terms of the lease, until either the title to the property transfers under FOST after completion of remediation or title transfers under a FOSET before completion of remediation.

Establishing and Enforcing Institutional Controls at Hunters Point Shipyard

The Role of Institutional Controls at Hunters Point Shipyard

Prior to any transfer or lease, early or not, the Navy must ensure that the property is suitable for the use intended and that the intended use is consistent with the protection of human health and the environment. Where hazardous substances remain on the property at the time of transfer at levels that are not suitable for unrestricted uses, such assurance can be achieved through Institutional Controls (ICs), a set of legal and administrative mechanisms to implement land use restrictions to limit the exposure of future landowner(s) and/or user(s) of the property to hazardous substances present on the property, and to ensure the integrity of remedial action. ICs are required on a property where the cleanup is determined to be complete even though residual levels of hazardous materials remain on the property at levels that would not allow for unlimited use and unrestricted exposure. ICs are expected to be required for HPS Phase II because the Navy and regulatory agencies in exercising their authority have determined that in order to be conservative (e.g., protective) in their evaluation of the property, particularly the areas composed of Bay Fill, they would require ICs for the residual levels of hazardous materials on the property. Implementation of ICs will allow the property to be developed for its intended use, subject to certain rules and regulations designed to prevent exposure to residual levels of hazardous materials. ICs include requirements for monitoring and inspections, and reporting to ensure compliance with land use or activity restrictions.

To implement ICs, the Navy anticipates that it will rely upon ICs in the form of environmental restrictive covenants as provided in the "Memorandum of Agreement between the United States Department of the Navy and the California Department of Toxic Substances Control" (Navy/DTSC MOA). The "Covenant(s) to Restrict Use of Property" will incorporate the land use restrictions into environmental restrictive covenants that run with the land and that are enforceable by DTSC against future transferees. The Quitclaim Deed(s) will include the identical land use and activity restrictions in environmental restrictive covenants that run with the land and that will be enforceable by the Navy and by regulatory agencies against all future transferees.[327]

In areas not planned for residential development at HPS Phase II, it is anticipated that the restrictions in the Covenant and Deed will prohibit use of the property as a residence, hospital for humans, schools for persons less than 21 years of age or day care center, unless the FFA Signatories approve a specific proposal for such a use., It is also anticipated that there will be a restriction against excavation or disturbance of soil or groundwater unless either a site-specific workplan is approved by the FFA Signatories, or the activity is consistent with an applicable "Risk Management Plan" (RMP) pre-approved by the FFA Signatories. A

[327] BRAC PMO, *Hunters Point Shipyard Parcel B Proposed Plan Fact Sheet*, June 2008. This document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

RMP specifies protocols and requirements for excavation, stockpiling, and transport of soil and for disturbance of groundwater as well as a system to respond to the discovery of previously unknown areas of contamination (e.g., an underground storage tank unearthed during normal construction activities). In a few specific areas, it is expected that there will be special restrictions associated with protecting the integrity of waste containment structures (e.g., caps) or ongoing treatment systems and with implementing the operation and maintenance plan for those remedies.

For parcels subject to early transfer, the restrictions may be more stringent until cleanup actions are completed, but restrictions are still expected to be imposed at most or all areas after remediation is complete because the ubiquitous nature of low levels of hazardous materials in Bay Fill makes it infeasible to remediate all of those materials. The specific mechanisms used to implement and enforce the activity restrictions in the Covenant and Deed(s) will be set forth in a Land Use Control Remedial Design document approved by the FFA Signatories.

If the Navy transfers property under a short-term lease or LIFOC, as explained previously, under CERCLA, the terms of the lease or LIFOC would contain restrictions similar, to those described above that would be contained in a Covenant and deed under an early transfer.

Although the Navy may transfer procedural responsibilities for enforcement of land use restrictions to another party by contract, property transfer agreement, or through other means, the Navy will retain ultimate responsibility.

Specific Institutional Controls Already Selected at HPS Phase II

The ICs included as part of the remedy selected in the Parcel B ROD Amendment are expected to form the basis for the ICs included in the RODs for the other parcels, so they are described in detail here. (As an example of this, the ROD for Parcel G imposes very similar ICs as the ROD for Parcel B). Figure III.K-2 indicates the locations in Parcel B that will require ICs—such as land use restrictions—to minimize potential human health and environmental risks after remediation is completed.

Except for the area called IR 7/18 (IR 7/18 site), Parcel B is intended as a mixed-use, residential community. Therefore, the ICs do not include a prohibition against residential use or other "sensitive uses" like schools, hospitals, and day care centers. Growing vegetables or fruits in native soil for human consumption and use of groundwater will be prohibited. In addition, the following general types of activities would be restricted: "land disturbing activity," which includes, but is not limited to, excavation of soil, road construction and infrastructure, demolition or removal of hardscape, any activity that involves movement of soil excavated from below the surface cover, and any other activity that causes or facilitates movement of known contaminated groundwater; alteration, disturbance, or removal of any component of a response or cleanup action; extraction of groundwater and installation of new groundwater wells; and removal or damage to security features. The ROD specifies that such restricted activities are allowed only if they are conducted in accordance with the requirements of a RMP approved by the FFA Signatories. At the time of transfer, it is expected that there will be two Parcel B RMPs specifying the processes to be used to gain approval for, and conduct, such restricted activities at different stages of the development: an RMP for use during Development and a Post-Development RMP.

Specific activity restrictions associated with certain contaminated areas would also be imposed. These may consist of the use of engineering controls or other design methods to ensure that areas that contain VOCs that could produce unacceptable indoor vapor inhalation risks from VOCs present in the subsurface are reduced to levels that are protective of human health. In addition, land use restrictions for property in IR Sites 7/18 would be reviewed and approved by the FFA Signatories in accordance with the covenants and deed restrictions. For IR Sites 7/18, a document such as an Operation and Maintenance Plan will identify any additional soil and radiological management issues, including restrictions on excavation in the radiologically impacted areas, and protection of the soil cap that will be placed at that location. Excavation within the potentially radiologically impacted area will require a separate site- and activity-specific work plan be prepared and submitted to the Navy and other FFA Signatories. Workplan(s) typically include descriptions of any necessary soil sampling and analysis, disposal of excavated soils, and restoration of the integrity of the soil cap after excavation.[328]

III.K.3 Regulatory Framework

Regulations Governing Hazardous Materials Release Sites

Federal Hazardous Materials Release Cleanup Requirements

The Navy is required to implement the investigation and cleanup of hazardous materials contamination in accordance with a complex framework of established federal laws and regulations in accordance with the FFA, with USEPA as the lead agency for hazardous substances remediation. Although federal environmental cleanup laws like CERCLA and RCRA do apply at the non-federal land at Candlestick Point, they are administered by state agencies and are described below.

State Hazardous Materials Release Cleanup Requirements

Navy remedial actions at HPS Phase II (and any remedial actions that may be necessary at Candlestick Point) must also comply with applicable state requirements. At the state level, DTSC administers laws and regulations related to hazardous waste and hazardous substances pursuant to Division 20, Chapters 6.5 and 6.8 of the *California Health and Safety Code* and Title 22 of the *California Code of Regulations* (CCR), which are the state equivalents of RCRA and CERCLA, respectively. The RWQCB enforces laws and regulations governing releases of hazardous substances and petroleum pursuant to pursuant to Division 20, Chapters 6.7, 6.75, and 6.8 of the *California Health and Safety Code* (Sections 25100, 25200 and 25300 et seq.), and the *Porter Cologne Water Quality Control Act* (Division 7, Section 13100 et seq. of the *California Water Code*) and CCR Title 23. In particular, the RWQCB focuses on all petroleum releases and those hazardous substance releases that may impact groundwater or surface water.

In addition, the CDPH is responsible for ensuring facilities that used, stored, or disposed of radiological materials are properly investigated, decontaminated, and decommissioned or licensed (or properly issued an exemption from such requirements) in accordance with state and federal laws and regulations, including

[328] BRAC PMO, *Hunters Point Shipyard Parcel B Proposed Plan Fact Sheet*, June 2008. This document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

the state Radiation Control Law (*California Health and Safety Code* Section 114960 et seq. and CCR Title 17, Division 1, Chapter 5. The licensing requirements (and, therefore, the process for approving exemptions from such requirements) administered by CDPH do not apply to federal facilities, but do apply when such facilities are transferred out of federal ownership. CDPH has indicated its willingness to consider granting an exemption from the licensing requirements to the City for areas where residual radiological materials may remain in place under a cap, like IR 7/18. The basis for the exemption would be that the requirements of CERCLA, and the ICs imposed pursuant to CERCLA would provide protection equivalent to the requirements of the license.

Local Hazardous Materials Release Cleanup Requirements

San Francisco Health Code Article 22A and its companion Article 21 of the *Public Works Code* (sometimes referred to as the Maher Ordinance) require an investigation of the potential presence of hazardous wastes that may be present in soil within historic fill areas at construction sites as a prerequisite for certain excavation and/or building requirements. As discussed above, Article 22A is intended to protect the health and safety of construction workers, residents, and occupants from risks associated with the potential presence of hazardous wastes in the soil by requiring a site assessment and mitigation of any risks identified as a condition for construction of a planned project. An Article 22A investigation is required if (1) more than 50 cubic yards of soil are to be disturbed, and (2) the project site is bayward of the 1851 high-tide line (i.e., in an area of Bay fill), as designated on an official City map, or (3) the site is at any other location in the City designated for investigation by the Director of the SFDPH. The reports are submitted to the Department of Public Works (DPW) and SFDPH. Article 22A regulations take effect at the time of the building permit application for projects located on filled land requiring excavation.

Under Article 22A, the Project Applicant must provide a site history to the SFDPH, and a professional geologist, civil engineer, or engineering geologist registered or certified by the State of California must conduct soil sampling to determine whether the soil contains hazardous waste using DTSC- or RWQCB-approved methods. A soils sampling and analysis report must be submitted to SFDPH (and DTSC, RWQCB, and other agencies if determined by SFDPH). If the soil sampling and analysis report indicates there are no hazardous wastes present in soil, the Article 22A requirements are assumed by SFDPH to be satisfied. If the soil sampling and analysis report or site history indicates hazardous wastes are, or may be, present in soil, a site-specific mitigation report must be prepared and submitted to SFDPH. The site mitigation report is required to contain the following information: a determination whether the hazardous wastes in soil are causing or are likely to cause significant environmental or health and safety risks, and if so, recommend measures that will mitigate the risks; and that the recommended site mitigation measures have been completed, which may include follow-up soil sampling and analysis.

Construction in those portions of Candlestick Point located bayward of the 1851 high tide line that would involve excavation of greater than 50 cubic yards of soil would be subject to the requirements of Article 22A. Because Article 22A requirements do not apply to Hunters Point Naval Shipyard, the SFDPH created Article 31. Article 31 was added to the *San Francisco Municipal Code* in 2004 (Ordinance 0303-04) in conjunction with the execution of a Disposition and Development Agreement (DDA) between the Agency and Lennar Urban pertaining to redevelopment of Parcel A (HPS Phase I) after the parcel was transferred from the Navy to the Agency in 2004. As explained in Attachment 12 to the DDA, the legislation was modeled on Article 22A. In general, Article 31 regulations establish the following: allowable residual soil

concentrations, and requirements for preparing plans and reports, including Site Evaluation, Supplemental Site Evaluation, Site Mitigation, Risk Evaluation, and Closure Reports. The regulations also establish a mechanism for SFDPH to verify compliance with certain requirements imposed in the previous EIR for development of HPS and establishes minimum criteria for various documents required by that EIR: DCPs, transportation and disposal plans, soil importation plans, health and safety plans, and stormwater and erosion control plans.

As presently drafted, Article 31 applies only to soil disturbances at Parcel A. However, it contains five sections that have no text other than a notation that they are reserved for Parcels B, C, D, E, and F. As discussed in Impacts below, the City anticipates that the requirements of the Land Use Control Remedial Design documents to be prepared as part of the CERCLA process and other aspects of the institutional controls, including the approval of Risk Management Plans, will incorporate many of the requirements for the other HPS parcels that are imposed on Parcel A by Article 31. Nevertheless, the City presently anticipates that, before additional parcels are transferred, it will amend Article 31 to add content to the relevant "Reserved" section(s). That additional content is expected to specify a similar process whereby SFDPH would assist permit-issuing departments of the City to verify that restrictions in deeds and covenants enforceable by the FFA Signatories and the Navy, and other mitigation measures identified by this EIR, have been complied with before the City issues excavation and other ground-disturbing permits and that compliance with the various measures continues for the duration of the construction.

Handling of Affected Groundwater

It may be necessary to pump shallow groundwater or "dewater" areas to facilitate construction. Discharges to the sewage system related to these activities are regulated by the DPW through Article 4.1, the Industrial Waste Ordinance of the *Public Works Code* as well as San Francisco Public Utilities Commission (SFPUC) batch wastewater discharge permit process. Groundwater from dewatering and/or cleanup activities must meet specific treatment standards before being discharged to the City sewage system under permits issued by the SFPUC. Permittees/dischargers typically also monitor the groundwater discharged to the sewer system and report regularly to the SFPUC.

If shallow groundwater were to be pumped directly into the Bay as a necessary by-product of construction dewatering, the discharger would be required to notify and obtain approval of the RWQCB, as described in Section III.M. Any groundwater proposed for discharge from the Project site into the Bay must meet strict water quality standards established by the San Francisco Bay Basin Plan as defined by the RWQCB, and may have to be treated before discharge into the Bay to avoid potential degradation of the Bay's water quality. Furthermore, dischargers are required to meet stringent monitoring standards established by the RWQCB (and to a certain extent, the State Water Resources Control Board) to ensure compliance under this permitting system.

Handling of Hazardous Waste

Hazardous waste may be generated from the Project site during construction and would need to be transported to a facility permitted to accept such waste. Management of specific hazardous wastes is addressed at the federal, state, and local levels. DTSC is authorized by USEPA to enforce the requirements of the federal RCRA. Under the state's Hazardous Waste Control Law, DTSC has adopted extensive regulations governing the generation, transportation, treatment, and disposal of hazardous wastes, which

are more stringent than the requirements of RCRA. The state requirements for hazardous waste management specified in the *California Health and Safety Code*, Chapter 6.5, Article 2,

San Francisco Health Code Article 22 provides for safe handling of hazardous wastes in the City. This article incorporates the state requirements for hazardous waste management specified in the *California Health and Safety Code*, Chapter 6.5, Article 2, and authorizes the SFDPH to implement the requirements of the *Hazardous Waste Control Act* related to hazardous waste generators in San Francisco. As provided by Article 22, the SFDPH has the authority to conduct inspections of any facilities where hazardous wastes are stored, handled, processed, disposed of, or treated to recover resources and must maintain records to document compliance with the *Hazardous Waste Control Act*. Hazardous wastes generated at a facility would be disclosed in the Hazardous Materials Certificate of Registration prepared for the facility. Hazardous wastes generated in areas undergoing remediation, if regulatory thresholds are exceeded, would be subject to Article 22.

Handling of Hazardous Materials

Hazardous materials that could be excavated from construction or activities in the Project site may require off-site transportation for disposal and/or treatment. Transportation and disposal of soil that is classified as hazardous waste would be subject to applicable federal and state regulations. The US Department of Transportation (US DOT) regulates hazardous materials transportation, including contaminated soil, between states, as described in Title 49 of the *Code of Federal Regulations*, and implemented by Title 13 of the CCR. The California Highway Patrol and the California Department of Transportation (Caltrans) are the state agencies with primary responsibility for enforcing federal and state regulations related to transportation within California. These agencies respond to hazardous materials (including contaminated soil) transportation emergencies. Together, these agencies determine container types to be used and grant licenses to hazardous waste haulers for hazardous waste transportation on public roads.

San Francisco Health Code Article 21 provides for safe handling of hazardous materials in the City. In addition to specifying permitting requirements for hazardous materials, Article 21 prohibits unauthorized releases of hazardous materials and specifies requirements for reporting an unauthorized release, inspections after an unauthorized release, addressing abandoned USTs or hazardous materials handling facilities, and closure of hazardous materials handling facilities. If removal of a permitted or previously unidentified abandoned or no longer used UST is required, tank closure would be required in accordance with Article 21.

Worker Safety

Occupational safety standards have been established in federal and state laws to minimize worker safety risks from both physical and chemical hazards in the workplace. California Department of Occupational Safety and Health Administration (Cal/OSHA) and the federal Occupational Safety and Health Administration (OSHA) are the agencies with primary responsibility for assuring worker safety in the workplace. Cal/OSHA has primary responsibility for developing and enforcing standards for safe workplaces and work practices in California in accordance with regulations specified in CCR Title 8. For example, under Title 8 CCR 5194 (Hazard Communication Standard), construction workers must be informed about hazardous substances that may be encountered. Compliance with Injury Illness Prevention Program requirements (Title 8 CCR 3203) would ensure that workers are properly trained to recognize workplace hazards and to take appropriate steps to reduce potential risks due to such hazards. This would be particularly important if previously unidentified contamination or buried hazards are encountered. If

additional investigation or remediation is determined to be necessary, compliance with Cal/OSHA standards for hazardous waste operations (Title 8 CCR 5192) would be required for those individuals involved in the investigation or cleanup work. A Site Health and Safety Plan must be prepared prior to commencing any work at a contaminated site or involving disturbance of building materials containing hazardous substances, to protect workers from exposure to potential hazards. Specific regulations related to these conditions are discussed below.

Building Demolition and Renovation

Many existing structures and buildings in the Candlestick Point and HPS Phase II are proposed for demolition. Hazardous wastes may be generated in the form of asbestos from friable building materials, lead-based paint on building surfaces, and lighting fixtures. In addition, previously unknown contamination, possibly the result of improper disposal or housekeeping activities, may be discovered as structures are demolished. Such hazardous wastes and materials would be subject to regulations governing hazardous waste and materials outlined above.

Asbestos in Structures and Buildings

Asbestos is regulated both as a hazardous air pollutant under the federal *Clean Air Act* regulations and as a potential worker safety hazard under the authority of Cal/OSHA. These regulations prohibit emissions of asbestos from asbestos-related manufacturing, demolition, or construction activities; require medical examinations and monitoring of employees engaged in activities that could disturb asbestos- containing building materials; specify precautions and safe work practices that must be followed to minimize the potential for release of asbestos fibers; and require notice to federal and local government agencies prior to beginning renovation or demolition that could disturb asbestos-containing building materials. The agencies with primary responsibility for asbestos safety are the Bay Area Air Quality Management District (BAAQMD), Cal/OSHA and OSHA, and USEPA.

Lead-Based Paint

Federal, state, and local laws and regulations govern handling of building materials that contain lead-based paint. OSHA Lead Construction Standards establish a maximum safe exposure level for the following types of construction work where lead exposure may occur: demolition or salvage of structures where lead or materials containing lead are present; removal or encapsulation of materials containing lead; and, new construction, alteration, repair or renovation of structures or materials containing lead. Typically, building materials with lead-based paint attached are not considered hazardous waste (Chapter II, Division 4.5, Title 22, CCR) unless the paint is chemically or physically removed from the building debris.

San Francisco Health Code, Chapter 34, Section 3407, establishes requirements for projects that disturb lead-based paint on the exterior of buildings or steel structures. It is implemented by the Department of Building Inspection (DBI). The ordinance contains performance standards, including a requirement to establish containment barriers that are at least as effective at protecting human health and the environment as those in the most recent *Guidelines for Evaluation and Control of Lead-Based Paint Hazards* promulgated by the US Department of Housing and Urban Development.

In addition, once a structure containing lead-based paint has been properly demolished there are federal and state requirements for future unrestricted residential reuse areas to verify that areas around a former structure were not contaminated with lead prior to or during the demolition process. For Parcel A at HPS, *San Francisco Health Code* Article 31 required submittal of a Lead Based Paint in Soil Sampling Report to analyze and, if found above action levels, remediate lead-based paint in soil. It is anticipated that Article 31 will be amended to require lead-based paint in soil to be addressed at HPS Phase II.

Lighting Wastes and PCBs

Lighting wastes may be classified as a hazardous waste if they contain concentrations of mercury, lead, or PCBs as a hazardous waste when the concentrations exceed specified limits in liquid or nonliquid substances. Fluorescent light ballasts that contain PCBs, regardless of size or quantity, are regulated as hazardous waste and must be transported and disposed of as hazardous waste. Such hazardous wastes and materials would be subject to regulations governing hazardous waste and materials outlined above.

Disturbance or Disposal of Shoreline Sediment

In San Francisco Bay Area, projects involving the disturbance or disposal of sediments (e.g., routine maintenance of a marina) in the Bay cannot be approved without concurrence from all permitting and commenting agencies in the Dredged Material Management Office (DMMO). The DMMO is a joint program of Bay Conservation and Development Commission (BCDC), RWQCB, State Lands Commission, the US Army Corps of Engineers San Francisco District (USACE), and the USEPA. Also participating are the California Department of Fish and Game (CDFG), the National Marine Fisheries Service, and the US Fish and Wildlife Service, who provide advice and expertise to the process. The purpose of the DMMO is to cooperatively review sediment quality sampling plans, analyze the results of sediment quality sampling, and make suitability determinations for material proposed for disposal in the Bay. The goal of this interagency group is to increase efficiency and coordination between the member agencies and to foster a comprehensive and consolidated approach to handling dredged material management issues. Through the DMMO, Project Applicants fill out one application form that the member agencies then jointly review at bi-weekly meetings before issuing their respective authorizations.[329]

The Dredge Material Reuse/Disposal Application serves as and is accepted for a number of permits, including *(a)* Section 404 or Section 10 dredging authorization by USACE, *(b)* an administrative dredging permit for BCDC, *(c)* the RWQCB water quality certification or waste discharge requirement, and *(d)* a dredging project lease from the State Lands Commission.

The roles, responsibilities, and jurisdictions of the DMMO agencies differ, depending primarily on the proposed dredged material disposal or reuse site. As a result, member agencies may play only an advisory role in certain aspects of the permitting process. Decisions made by the DMMO do not in any way supersede the primary roles of the permitting agencies, which remain free to accept or reject recommendations, including those of the DMMO staff. In practice, however, the discussions at the DMMO meetings help inform the permitting agencies of specific concerns and issues of the member agencies, often before finalization of project documents. The DMMO facilitates the processing of dredging

[329] SFBCDC, Long Term Management Strategy for the Placement of Dredged Material in the San Francisco Bay, Memo, April 18, 2008.

permit applications within existing laws, regulations, and policies. It was specifically designed to provide a mechanism for consistent review of permit applications through coordinated efforts by DMMO member agencies. It also provides a mechanism to allow the involvement and participation of permit applicants and interested parties during the application process. All applicable regulatory authority and processes of the member agencies remain in full force and effect.[330]

Air Emissions Associated with Development of Hazardous Materials Release Sites

The BAAQMD is primarily responsible for planning, implementing, and enforcing federal and state ambient air quality standards in the San Francisco Bay Area. BAAQMD regulates both criteria air pollutants and toxic air contaminants (refer to Section III.H.3 [Regulatory Framework] [in Air Quality]). The state Asbestos Airborne Toxic Control Measure (ATCM) for Construction, Grading, Quarrying, and Surface Mining Operations is also regulated by the BAAQMD. BAAQMD regulates particulate matter from construction activities and requires the implementation of various dust control measures to keep small-diameter particulates, or $PM_{10,}$ levels to a minimum.

In addition, the City has adopted Article 22B, Construction Dust Control Ordinance (Dust Ordinance) that requires stringent controls to minimize dust emissions. The Dust Ordinance was adopted in July 2008 and requires that all site preparation work, demolition, or other construction activities within the City to comply with specific dust control measures. For projects over one half-acre, the Dust Control Ordinance requires that the Project Applicant submit a Dust Control Plan (DCP) for approval by the SFDPH prior to issuance of a building permit by DBI.

The Dust Control Ordinance requires Project Applicants and responsible contractors for construction activities to control construction dust on the site or implement other practices that result in equivalent dust control that are acceptable to the Director. Dust suppression activities may include watering all active construction areas sufficiently to prevent dust from becoming airborne; increased watering frequency may be necessary whenever wind speeds exceed 15 miles per hour. In addition, *San Francisco Health Code* Article 31 required submittal of a DCP for the Parcel A development. It is anticipated that Article 31 will be amended to include a requirement for submittal of a DCP for HPS Phase II (refer to Section III.H.3 [in Air Quality] for additional information).

Naturally Occurring Asbestos

The California Air Resources Board ATCM for Construction, Grading, Quarrying, and Surface Mining Operations is intended to protect public health and the environment by requiring the use of best available dust control measures to prevent off-site migration of naturally occurring asbestos-containing dust from road construction and maintenance activities, construction and grading operations, and quarrying and

[330] Dredge Material Management Office, DMMO Annual Report January 1st through December 31st 2003, April 2004. http://www.spn.usace.army.mil/conops/2003AnnualReport.pdf (accessed December 4, 2008).

surface mining operations in areas of ultramafic rock,[331] serpentine,[332] or asbestos.[333] The ATCM applies to grading or excavation activities, which would involve the excavation of bedrock or fill materials potentially containing naturally occurring asbestos.

For construction activities disturbing less than one acre of area underlain by these types of bedrock potentially containing naturally occurring asbestos, specific dust control measures must be implemented in accordance with the ATCM before construction begins and each measure must be maintained throughout the duration of the portion of the construction project when these types of bedrock are being disturbed. For construction activities disturbing greater than one acre of area underlain by these types of bedrock potentially containing naturally occurring asbestos, construction contractors are required to prepare an Asbestos Dust Mitigation Plan (ADMP) specifying measures that will be taken in an attempt to ensure that no visible dust crosses the property boundary during construction. The ADMP must be submitted to and approved by the BAAQMD prior to the beginning of construction, and the site operator must ensure the implementation of all specified dust control measures throughout the construction project. In addition, the BAAQMD may require air monitoring to monitor for off-site migration of asbestos dust during construction activities and may change the plan on the basis of the air monitoring results.

Section III.H describes construction dust, toxic air contaminants, and airborne asbestos regulations further.

Hazardous Materials Use During Occupancy of the Project

The management of hazardous materials is regulated under a number of laws at federal, state, and local levels through programs administered by the USEPA, agencies within the California Environmental Protection Agency (Cal/EPA) such as the DTSC and the RWQCB, US DOT, California Highway Patrol, federal and state Occupational Safety and Health agencies (OSHA), and the San Francisco Department of Public Health (SFDPH).

Many of the state laws and regulations previously described for the cleanup of hazardous materials release sites, which implement federal laws, would equally apply to the routine use of hazardous materials and the generation of hazardous waste at the Project and are not repeated here. These include the state's Hazardous Waste Control Law administered by DTSC, Cal/OSHA workplace regulations, and federal and state DOT transportation requirements. There are additional state and local laws and regulations that would apply to hazardous materials during Project operation, as described below.

Hazardous materials are required to be stored in designated areas designed to prevent accidental release to the environment. *California Building Code* (CBC) requirements prescribe safe accommodations for materials that present a moderate explosion hazard, high fire or physical hazard, or health hazards.

---

[331] Ultramafic rocks are formed in high temperature environments well below the surface of the earth.

[332] Serpentine is a naturally occurring group of minerals that can be formed when ultramafic rocks are metamorphosed during uplift to the earth's surface. Serpentinite is a rock consisting of one or more serpentine minerals. This rock type is commonly associated with ultramafic rock along faults such as the Hayward Fault. Small amounts of chrysotile asbestos, a fibrous form of serpentine minerals, can be common in serpentinite.

[333] Asbestos is a term used for several types of naturally occurring fibrous minerals found in many parts of California.

The *Hazardous Materials Management Act* requires that businesses handling or storing certain amounts of hazardous materials prepare a Hazardous Materials Business Plan (HMBP), which includes an inventory of hazardous materials stored on site (above specified quantities), an emergency response plan, and an employee-training program. Businesses that use, store, or handle 55 gallons of liquid, 500 pounds of a solid, or 200 cubic feet of a compressed gas at standard temperature and pressure require this business plan (i.e., the stadium, and/or marina).

During Project operation, for activities subject to such requirements, these laws and regulations would be monitored and enforced by the City in accordance with specific articles established in the *San Francisco Health Code*, as summarized below.

San Francisco Health Code Article 21

Article 21 of the *San Francisco Health Code* provides for safe handling of hazardous materials in the City. In accordance with this article, any person or business that handles, sells, stores, or otherwise uses hazardous materials in quantities exceeding specified threshold amounts would be required to obtain and keep a current hazardous materials certificate of registration and to implement an HMBP submitted with the registration application. Facilities with USTs are also required to obtain a permit to operate the tank. In addition to specifying permitting requirements for hazardous materials and USTs, Article 21 prohibits unauthorized releases of hazardous materials and specifies requirements for reporting an unauthorized release, inspections after an unauthorized release, addressing abandoned USTs or hazardous materials handling facilities, and closure of hazardous materials handling facilities.

This Article helps protect the health and safety of the general community and emergency response personnel, such as fire fighters and paramedics. Data on hazardous materials use are stored in a citywide computer system and can be made available to emergency responders. The information assists emergency responders to assess and resolve hazardous materials incidents quickly and safely. Inspections are performed by the City every one to two years or upon complaint.

Article 21 incorporates the California Underground Storage Tank Regulations specified in the *California Health and Safety Code*, Chapters 6.7 and 6.75; Hazardous Materials Release Response Plans and Inventory Regulations requiring preparation of an HMBP, and specified in the *California Health and Safety Code*, Chapter 6.95, Article 1; Aboveground Petroleum Storage Tank Regulations requiring preparation of a SPCC plan, and specified in the *California Health and Safety Code*, Section 25270.5; and hazardous materials management provisions of the *Uniform Fire Code* requiring Hazardous Materials Inventories specified in Sections 8001.3.2(a) and 8001.3.3(a). It also provides for additional stricter local requirements.

San Francisco Health Code Article 22

San Francisco Health Code Article 22 provides for safe handling of hazardous wastes in the City. This article incorporates the state requirements for hazardous waste management specified in the *California Health and Safety Code*, Chapter 6.5, Article 2, and authorizes the SFDPH to implement the requirements of the *Hazardous Waste Control Act* related to hazardous waste generators in San Francisco. Hazardous wastes generated at a facility would be disclosed in the Hazardous Materials Certificate of Registration and HMBP prepared for the facility in accordance with Article 21 of the *San Francisco Health Code* (described above).

San Francisco Department of Public Health Hazardous Materials Unified Program Agency

Cal/EPA has adopted regulations implementing a "Unified Hazardous Waste and Hazardous Materials Management Regulatory Program" (Unified Program). The six program elements of the Unified Program are hazardous waste generators and hazardous waste on-site treatment, underground storage tanks, above-ground storage tanks, hazardous material release response plans and inventories, risk management and prevention program, and Uniform Fire Code hazardous substances management plans and inventories. The program is implemented at the local level by a local agency—the Certified Unified Program Agency (CUPA). The CUPA is responsible for consolidating the administration of the six program elements within its jurisdiction.

The San Francisco Department of Public Health Hazardous Materials Unified Program Agency (HMUPA) has been granted authority by the State under the Unified Program to enforce the program element regulations pertaining to hazardous materials in the City. These include permitting for hazardous materials storage, underground storage tanks, and hazardous waste generation under the DPH Certificate of Registration Program, described below.

A Hazardous Materials Compliance Certificate is awarded to businesses registered with the SFDPH that provide required annual information as applicable to their facility including: hazardous materials and wastes inventories, use, materials reduction, on-site treatment, and employee training; facility maps; emergency response procedures; underground storage tanks management (including forms, leak detection monitoring program, and financial responsibility certificates); medical wastes; regulated substances; aboveground storage tanks; diesel backup generators; and chlorofluorocarbon recovery and recycling. Under the DPH HMUPA, building contractors temporarily storing hazardous materials at a construction site must also apply and receive a HMUPA certificate for storage of hazardous materials during construction and must provide the appropriate fees.

Other Applicable State Regulations

Transportation of Hazardous Materials

CCR Section 31303 requires that when hazardous materials are transported on state or interstate highways, the highway(s) that offer the shortest overall transit time possible shall be used, and as required by federal and state laws, all other hazardous materials transportation regulations must be followed, such as US DOT regulations for packaging and handling hazardous materials to prevent accidental spills of hazardous materials during transit.

Radioactive Materials

Medical and dental offices use X-ray equipment, and practitioners may use small quantities of radioactive materials such as diagnostics and radiopharmaceuticals. The types and quantities of radioactive materials would be minimal. The CDPH is responsible for ensuring facilities that use, store, or dispose of radiological materials are properly licensed (or properly issued an exemption from such requirements) in accordance with state and federal laws and regulations, including the state Radiation Control Law (*California Health and Safety Code* Section 114960 et seq. and CCR Title 17, Division 1, Chapter 5. The Radiologic Health Branch

(RHB) licenses institutions that use radioactive materials and radiation-producing equipment, such as X-ray equipment. To maintain a radioactive materials license, an institution must meet training and radiation safety requirements and be subject to routine inspections.

San Francisco General Plan

The *San Francisco General Plan* (1996) provides long-term guidance and policies for maintaining and improving the quality of life and the man-made and natural resources of the community. The Community Safety chapter and the Environmental chapter of the *San Francisco General Plan* contain the following policies relating to hazardous materials:

Community Safety

Policy 2.12 Enforce state and local codes that regulate the use, storage and transportation of hazardous materials in order to prevent, contain and effectively respond to accidental releases.

Environmental Protection

Policy 1.4 Assure that all new development meets strict environmental quality standards and recognizes human needs.

San Francisco Bay Plan

Refer to Section III.B for a description of the Bay Plan. The objectives and policies of the Bay Plan concerning hazards that are relevant to the Project are listed below:

Part IV: Development of the Bay and Shoreline: Safety of Fills

2. Even if the Bay Plan indicates that a fill may be permissible, no fill or building should be constructed if hazards cannot be overcome adequately for the intended use in accordance with the criteria prescribed by the Engineering Criteria Review Board.

III.K.4 Impacts

On-site workers and other persons visiting or occupying a site are potentially at risk at sites where hazardous materials have been used or where there could be an exposure to such materials as the result of the presence of unidentified fill materials or historic uses of a site, such as at locations in the Project site. Ecological communities, such as avian and terrestrial habitats and the aquatic environment, may also be at risk, depending on the type of populations and locations relative to potential exposure sources. This section addresses the potential impacts on construction workers, the public, and the ecological environment from exposure to hazardous materials at Candlestick Point and HPS Phase II, including shoreline/intertidal improvements such as rock wall buttresses and riprap-protected slopes that could disturb sediments. Section III.N (Biological Resources) and Section III.M (Hydrology and Water Quality) provide more detailed analysis about construction of Project features that could affect offshore water quality. Potential impacts associated with construction of infrastructure off site are also evaluated.

This section also describes the nature and extent of routine hazardous materials use in existing land uses in the Project site (e.g., PDR [production, distribution, and repair] uses and mixed-use development), and the potential for upset and accident conditions in which hazardous materials could inadvertently be

released. The impact analysis identifies how proposed new land uses would introduce additional operational components (e.g., R&D) that would increase the types and amounts of hazardous materials routinely used, stored, or transported to, from, and within the Project site, and the extent to which existing and future populations could be exposed to hazardous materials.

Significance Criteria

The City and Agency have not formally adopted significance standards for impacts related to hazards and hazardous materials, but generally consider that implementation of the Project would have significant impacts if it were to:

- K.a Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials
- K.b Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment
- K.c Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school
- K.d Be located on a site that is included on a list of hazardous materials sites compiled pursuant to *Government Code* Section 65962.5 and, as a result, create a significant hazard to the public or the environment
- K.e For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, result in a safety hazard for people residing or working in the project area
- K.f For a project within the vicinity of a private airstrip, result in a safety hazard for people residing or working in the project area
- K.g Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan
- K.h Expose people or structures to a significant risk of loss, injury, or death involving fires

Analytic Method

Scope of Impact Analysis for Hazardous Materials Release Sites

The presence of hazardous materials is related to both the industrial and commercial history of many locations within the Project site as well as the development of the current shoreline through the placement of fill materials. The existing conditions, as described in the Setting (including the status of remediation plans under regulatory agency oversight), provide the baseline against which to compare the effects of the Project. The following impact analyses focus on the potential human health effects associated with hazardous materials that could be encountered during construction, during development (e.g., some land uses would be occupied while new locations are being developed and/or remediated), and at full build-out of the Project.

The analysis also evaluates potential health effects due to materials such as asbestos, lead, or PCBs that could be present in buildings that would be demolished or renovated, or in soil or rock that would be excavated or graded. The potential for previously unidentified contamination to be encountered and possible adverse effects, if any, are qualitatively analyzed as well.

The analysis presented in this section is based on conditions as they existed in 2007 through 2009, based on published reports and agency databases available in 2009. As noted in the Introduction, remediation of hazardous materials releases identified in HPS Phase II is taking place through a regulatory process that the Navy is required to implement under CERCLA irrespective of whether or not HPS Phase II part of the Project is implemented.

Risk Estimates and Cleanup Levels

Various regulatory agencies, such as the USEPA, RWQCB, DTSC, and OSHA and Cal/OSHA are responsible for developing and/or enforcing risk-based standards to protect the public and the environment. The current regulatory view of redevelopment where chemical and radiological constituents are present in the soil or groundwater is that the decisions regarding cleanup and future site use should be based on actual and reasonably projected risks presented by individual sites. This risk-based approach is marked by a focus on planned land uses, a recognition that all sites do not present the same risk, the understanding that the actual risks posed by a site are a function of the populations that could be present and the activities they could be engaged in, and an acknowledgment that many risks can be reduced and/or eliminated through the implementation of controls placed on the future use of the land, including through legally enforceable restrictions on use and risk management plans.

Depending on the types of chemicals present and potential pathways through which individuals might be exposed to the chemicals, contaminants in soil or groundwater can often be left in place or cleaned up to a degree that does not pose a threat to human health or the environment. The risk estimates take into consideration such factors as the concentration and further potential migration of contaminants, potential hazards to remediation workers and nearby populations, and potential exposures to the public, based on future land use. The risk-based decision-making relies on the preparation of risk-based evaluations to quantify potential exposures and resultant potential adverse health effects. For instance, in an area of known soil contamination where a park is to be constructed, once the park is in place it would provide a barrier to prevent direct access to the contamination. The assessment of whether soil and groundwater is contaminated and requires remediation is guided by using established risk assessment procedures and comparing concentrations of potential contaminants (chemical or radiological), obtained through site sampling, to regulatory standards or to site-specific standards. Numerical risk values are estimated for cancer-causing compounds and for non-cancer-causing compounds. At HPS Phase II, where there is identified contamination requiring the preparation of a risk assessment, the risk assessment calculations for soil and groundwater were based on exposure rates recommended by USEPA and DTSC. As part of the CERCLA remedial process for HPS, the Navy, in consultation with the FFA Signatories, adopted a conservative and protective approach that estimates the highest health risks that are reasonably expected at HPS. The human health risk assessments assumed a one-in-a-million (1×10^{-6}) excess cancer risk[334] threshold for developing suitable and protective remedial action alternatives. Unlike cancer risk estimates, the measure used to describe the potential for noncarcinogenic toxic effects to occur is expressed in terms of a Hazard Index (HI). The HI assumes that there is a level of exposure below which it is unlikely, even for sensitive populations, to

[334] Carcinogenic compounds are present in daily life and present a risk of exposure to individuals; there is a cumulative risk from numerous environmental sources. The risk criterion (1x10-6) and the quantified values that are compared to the criterion represent the *probability* of occurrence that exposure to carcinogenic materials would exceed—in others words, would be in addition to—existing risk.

experience adverse health effects. Adverse health effects are not anticipated when chronic and acute hazard indices are less than one. The final calculated risk values represent a conservative probability of occurrence.

The contaminants in HPS Phase II, and risk assessments that were used in developing cleanup levels, are an existing condition. As described in the Setting, the cleanup levels and remedial plans have been or will be approved by the FFA Signatories (and by the Governor for the case of an early transfer) at HPS Phase II. Remediation to achieve those levels will occur regardless of whether the Project is implemented. The cleanup will follow actions and timelines that have been, or will be, coordinated between the Navy and FFA Signatories for HPS Phase II. However, this analysis does evaluate the potential impacts of the limited remedial activities that may be conducted by the Agency or Project Applicant in conjunction with development activities, as described below.

Figure III.K-5 (Hunters Point Shipyard Phase II Navy Parcel Overlay) illustrates the relationship of the Project districts to the existing Navy cleanup parcel designations.

Management of Hazardous Materials Contamination Risks During Development

The analysis in this EIR focuses on whether the physical development of the Project could expose construction and maintenance workers, visitors, or occupants, or ecologic systems, to potential hazards associated with identified contaminants throughout the life of the Project.

Further, for HPS Phase II, the analysis reflects the requirements of the RODs approved to date and the stated intentions of the Navy, USEPA, DTSC (and through DTSC, CDPH) and the RWQCB to require through the CERCLA process that before any Project development activity occur at HPS Phase II, appropriate and legally enforceable environmental restrictions on uses and activities at the Project site (as described above) will be in place and applicable to that activity, whether in the form of a recorded covenant, deed provision, or lease term. Such restrictions will have been approved by the FFA Signatories as being sufficient under CERCLA and other applicable laws to ensure protection of human health and the environment during and after the development activity process, and the FFA Signatories will have approved a Land Use Control Remedial Design Document, or similar documents, identifying the specific mechanisms to be used to implement and enforce the restrictions. Although these restrictions and enforcement mechanisms will be established independent of this EIR, the mitigation measures identified in this EIR will provide redundant protection by requiring all Project development activities as well as all activities and uses conducted after the completion of development, to be in compliance with these environmental restrictions.

Such restrictions are expected to be applicable both to development activities that take place before remediation is complete (e.g., if the property is subject to an early transfer), and to development activities that take place after remediation is complete (e.g., if the property is transferred after a FOST, or if the property is leased and limited development activities like asbestos and lead-based paint abatement or building demolition are permitted under the terms of the lease). Although use and activity restrictions may be more stringent before remediation is complete, it is expected that restrictions will still be necessary after remediation is complete in most or all areas of HPS Phase II.

- Figure III.K-6 (Status of CERCLA Process) provides a map of the various Navy parcels at HPS Phase II and illustrates the steps in the CERCLA process and the current status of the parcels in that process.

STATUS OF CERCLA PROCESS

Development Schedule

Development is proposed to occur over a period of 20 or more years; it is likely development and occupancy of some portions of the Project would occur at the same time as demolition and construction would occur in other portions of the Project site in which contaminated soils or groundwater have been identified. Relatively few individuals would be exposed to the potential contaminated material during the initial construction. During later periods of construction, existing uses may remain, some interim uses may be occupied, and some of the proposed commercial, retail, open space, and residential uses would be completed and occupied. Consequently, an increasingly greater number of people could be affected by construction activities involving the disturbance of contaminated soil or groundwater during later development. This could be a particular issue in the residential portions of HPS Phase II, where construction in contaminated soils may occur near occupied residential units.

Existing uses adjacent to the Project site (e.g., in HPS Phase I) and new interim uses in the Project site during development present issues similar to those of development that occurs over a period of years. The issues would be whether there would be potentially significant impacts to people occupying sites in the Project (1) while remediation of nearby hazardous material sites has not been completed, and (2) while development that would disturb soils and/or shallow groundwater was occurring at adjacent or nearby sites in the Project. Those impacts would be of greater concern than impacts following build-out, because exposure to chemicals in soil and/or groundwater would be more likely to occur during, rather than after, development. Thus, the analysis of potential human health and ecological effects that could occur during construction applies to existing, remaining, interim uses, and to permanent uses occupied in early or middle periods of development.

Impacts from adjacent and nearby hazardous material release sites are carefully analyzed in the transfer documents (e.g., FOSTs, FOSETs, and FOSLs) prepared to comply with the requirements of CERCLA. For example, the FOST for Parcel A described in detail the potential impact on future residents of Parcel A from the hazardous material release sites where remediation had not been completed on other adjacent parcels, particularly what is now Parcel E-2, and concluded that there would not be significant impacts on Parcel A from Parcel E-2 or other adjacent parcels at HPS Phase II.

Scope of Impact Analysis for Hazardous Materials Use During Occupancy

The analysis assumes nearly all Project uses would involve the routine use of hazardous materials at varying levels, including uses at existing PDR and mixed-use land uses, and that there is the potential that such use could result in a release of hazardous materials. Quantification of precise amounts of additional hazardous materials use associated with new proposed uses is not practical at this stage of Project development. Therefore, the analysis qualitatively evaluates broad categories of hazardous materials use, ranging from R&D in which a wide variety of hazardous materials would be used, to facilities such as the proposed stadium where fuels and maintenance products would comprise the majority of hazardous materials, to smaller-scale users, such as artists' studios and households. For purposes of the analysis, compliance with existing federal, state, and local laws and regulations pertaining to hazardous materials management are presumed to be sufficient to minimize health and safety risks, and that state and local agencies would be expected to continue to enforce applicable requirements to the extent they do so now.

Existing Regulatory Framework

The following impact analyses also relies on compliance with applicable site development regulations including, but not limited to, the requirements imposed in deeds, leases or recorded land use covenants, RMPs, and the requirements of the federal, state, and local laws and regulations that have been summarized in Section III.K.3.

Construction Impacts

Impact HZ-1: Exposure to Known Contaminants

Impact of Candlestick Point

Impact HZ-1a **Construction at Candlestick Point bayward of the historic high tide line would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of soil and/or groundwater with known contaminants from historic uses. (Less than Significant with Mitigation)** ***[Criterion K.b]***

Types of Construction and Development Activity Anticipated at Candlestick Point

Implementation of Candlestick Point would involve extensive construction to accommodate new development within that area, as shown in Figure II-4 (Proposed Land Use Plan) and in Table II-2 (Existing and Proposed Uses) in Chapter II. Site preparation would include deep excavations for large structures such as residential towers, with plans to use the cut material elsewhere within the Project site as fill; installation of foundation piles; trenching for utility lines; grading and compaction; and other earth-disturbing activities. Additionally, there would be roadway improvements, including rebuilding Harney Way and other new roadways within the site. As stated in the Setting, the current site of Candlestick Park and associated parking, CPSRA, an area north of Yosemite Slough (North Park Area), an area southeast of Harney Way (Last Port Area), and Hunters Point Expressway (ring road) comprising approximately 235 acres was investigated in 1998.

Portions of Candlestick Point with a Potential for Exposure

As described in the Setting section above, there are no sites with known contamination requiring remediation at Candlestick Point. At Candlestick Point, results of soil and groundwater sampling taken at depths of up to 15 feet detected organic compounds and metals at various depths and locations, indicating the chemicals were associated with fill materials. A human health risk evaluation concluded that the presence of the detected chemicals in soil and groundwater did not pose an unacceptable carcinogenic or non-carcinogenic risk to future workers or visitors, nearby residents or workers, or recreational uses in the Bay. The report concluded no further action was necessary. The report did note that if excavation to depths greater than 15 feet were planned, additional sampling, risk evaluation, or methane monitoring, may be appropriate. A Phase I ESA conducted in 2006 and updated in 2009 concluded that releases or areas of recognized environmental conditions were not observed during either of these Phase I assessments. DPR staff have also indicated that, decades ago, individuals may have disposed of household hazardous waste on portions of the CPSRA, although DPR does not have any files indicating that a state-regulated landfill was on-site. The ESAs do recommend that a soil management plan be developed prior to redevelopment

to describe procedures to follow in the event unexpected contamination is encountered during construction activities and if appropriate, comply with Article 22A.

Although there are no known releases of hazardous materials requiring remediation in the portions of Candlestick Point bayward of the 1851 high-tide line, the detection of low-levels of hazardous materials in 1998 and general knowledge of the types of material that can be in Bay fill lead to the conclusion that there is a potential for exposure to hazardous materials from development activity in these areas.

Since the potential source of hazardous materials that could require remediation at Candlestick Point is fill material, and the portions of Candlestick Point located landward of the 1851 high tide line are not composed of fill material, and the ESAs for these portions did not identify any other sources, there is no significant potential for exposure to hazardous materials from development activities at these areas. The discussion of Candlestick Point in the rest of this section, therefore, applies only to the portions of Candlestick Point located bayward of the 1851 high tide line.

Application of the Article 22A Site Evaluation and Mitigation Process to Potential Construction Impacts at Candlestick Point

The requirement for a site assessment prior to obtaining a grading permit for new construction would be triggered by Article 22A for sites at Candlestick Point located bayward of the 1851 high tide line, which are the Candlestick Point North and Candlestick Point South districts, comprising the bulk of the area previously investigated in 1998. Compliance with Article 22A requirements would ensure current conditions are assessed in the area previously investigated in 1998, and that they are assessed in light of the specific planned depths of excavation. As stated below on page III.K-68, Hunters Point Shipyard soil shall not be used for grading adjustments within CPSRA, but may be reused on the Shipyard to the extent permissible under the Navy remedial program.

Article 22A requires further investigation and site mitigation if a release of hazardous materials is indicated by the environmental assessment. The Article 22A soil analysis report would be submitted to the SFDPH. If concentrations of chemicals are found above certain criteria via the Article 22A soil sampling process, a site mitigation plan is required to be submitted to and approved by the SFDPH and would also include the planned disposal method for any wastes generated. The site mitigation plan would specify the actions that must be implemented to mitigate the risks posed by the identified release of hazardous materials. Site mitigation plans are described in more detail in the discussion of mitigation measure MM HZ-1a below.

To reduce impacts related to exposure to known contaminants at Candlestick Point from construction activities, the following mitigation measure shall be implemented.

MM HZ-1a *Article 22A Site Mitigation Plans. (Applies only to Candlestick Point.) Prior to obtaining a site, building or other permit from the City for development activities involving subsurface disturbance at portions of Candlestick Point bayward of the high tide line, the Project Applicant shall comply with the requirements of San Francisco Health Code Article 22A. If the site investigation required by Article 22A (or, in the case of development activity in CPSRA, which is not subject to Article 22A, a comparable site investigation that is carried out to comply with this measure, and which involves notification to California State Parks if a site mitigation plan is prepared), indicates the presence of a hazardous materials release, a site mitigation plan must be prepared. The site mitigation plan must specify the actions that will be implemented to mitigate the significant environmental or health and safety*

risks caused or likely to be caused by the presence of the identified release of hazardous materials. The site mitigation plan shall identify, as appropriate, such measures as excavation, containment, or treatment of the hazardous materials, monitoring and follow-up testing, and procedures for safe handling and transportation of the excavated materials, or for protecting the integrity of the cover or for addressing emissions from remedial activities, consistent with the requirements set forth in Article 22A.

- *To the extent that Article 22A does not apply to state-owned land at CPSRA, prior to undertaking subsurface disturbance activities at CPSRA, the Agency and the California Department of Parks and Recreation shall enter into an agreement to follow procedures equivalent to those set forth in Article 22A for construction and development activities conducted at Candlestick Point State Recreation Area.*

Implementation of mitigation measure MM HZ-1a would reduce effects related to exposure of known contaminants at Candlestick Point, including construction activities at CPSRA, by requiring compliance with Article 22A or an equivalent process. Any remedial activities and the associated safety protocols and control measures would be similar to those described in Table III.K-2 (Remedial Actions, Potential Environmental Effects, and Methods to Reduce Effects). At a Bay Fill site like Candlestick Point, a site mitigation plan may instead take a similar approach to the one taken by the Navy to address Bay Fill materials at HPS Parcel B. As described above, that approach involved Institutional Controls and implementation of Risk Management Plans with the placement of recorded deed restrictions on the property, if necessary, to limit uses or activities on the property to ensure any significant environmental or health and safety risk is mitigated. Implementation of this measure would ensure that potential adverse effects on human health and the environment from construction activities disturbing known subsurface hazards would be reduced to a less-than-significant level.

Impact of Hunters Point Shipyard Phase II

Impact HZ-1b **Construction at HPS Phase II would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of soil and/or groundwater with known contaminants from historic uses. (Less than Significant with Mitigation)** ***[Criteria K.b and K.d]***

Implementation of HPS Phase II would involve construction to accommodate new development within that area, as shown in Figure II-4 and in Table II-2 in Chapter II. Site preparation would include deep excavations for large structures such as residential towers; installation of foundation piles; trenching for utility lines; grading and compaction; and other earth-disturbing activities. This impact specifically addresses potential hazards associated with landward soils that could be encountered during construction. Potential impacts associated with sediment that could be disturbed during shoreline improvements are evaluated in Impact HZ-10.

As described in the Setting, HPS Phase II is going through a remediation process independent of the Project, and property could transfer or be leased or accessed for limited activities, such as installation of infrastructure, before or after completion of remediation activities. To the extent that the property under development contains hazardous materials at the time of development, potentially significant impacts could result from exposure to such hazardous materials by workers, occupants, and visitors if controls are not in place to manage the risks from such exposure.

As discussed above, the Navy, USEPA, DTSC, RWQCB, and CDPH will, independent of the Project and this EIR, require that before any Project development activity occurs at HPS, appropriate and legally enforceable environmental restrictions on uses and activities at the Project site be in place and applicable to that activity, whether in the form of a recorded covenant, deed provision, easement, or lease term. The nature of the expected restrictions are described in detail in the "Regulatory Process for Cleanup Process at HPS Phase II" in Section III.K.2, above. Such restrictions will have been approved by the FFA Signatories as being sufficient under CERCLA and other applicable laws to ensure protection of human health and the environment during and after the development activity process, and the FFA Signatories will have approved a Land Use Control Remedial Design Document, or similar documents, identifying the specific mechanisms to be used to implement and enforce the restrictions. Although these restrictions and enforcement mechanisms will be established independent of this EIR, the mitigation measures identified in this EIR, including mitigation measure MM HZ-1b, would provide redundant protection by requiring that all Project development activities and uses conducted after the completion of development be in compliance with these environmental restrictions.

Such restrictions are expected to be applicable both to development activities that take place before remediation is complete (e.g., if the property is subject to an early transfer), and to development activities that take place after remediation is complete (e.g., if the property is transferred after a FOST), or if the property is leased or accessed through a license or easement and limited development activities like asbestos and lead-based paint abatement or building demolition are permitted under the terms of the lease, or infrastructure is installed under a license or easement). Although use and activity restrictions may be more stringent before remediation is complete, it is expected that restrictions will still be necessary after remediation is complete in most or all areas of HPS Phase II.

To reduce impacts related to exposure to known contaminants from construction activities at HPS Phase II to a less-than-significant level, the following mitigation measure shall be implemented.

MM HZ-1b *Compliance with Requirements Imposed by Cleanup Decision Documents and Property Transfer Documents. (Applies only to HPS Phase II) Prior to obtaining a grading, excavation, site, building or other permit from the City for development activity at HPS Phase II involving subsurface disturbance, the Project Applicant shall submit documentation acceptable to the San Francisco Department of Public Health that the work will be undertaken in compliance with all notices, restrictions, and requirements imposed pursuant to a CERCLA ROD, Petroleum Corrective Action Plan, FOST, FOSET or FOSL, including notices, restrictions, and requirements imposed in deeds, covenants, leases, easements, and LIFOCs, and requirements set forth in Land Use Control Remedial Design Documents, Risk Management Plans, Community Involvement Plans, and health and safety plans. Such restrictions, imposed by federal and state regulatory agencies as a condition on the Navy transfer of the property to the Agency, will ensure that the property after transfer will be used in a manner that is protective of the environment and human health. The City/Agency may choose to implement this measure by requiring these actions as part of amendments to San Francisco Health Code Article 31, which currently sets forth procedural requirements for development in HPS Phase I, or through an equivalent process established by the City or Agency.*

With implementation of this mitigation measure, for areas not planned for residential development, the restrictions in the Covenant and Deed will prohibit use of the property as a residence, hospital, school, or day care center, unless the FFA Signatories approve a specific proposal for such a use. In most non-

residential areas, and residential areas, it is anticipated that there will be a restriction against excavation or disturbance of soil or groundwater unless either a site-specific workplan is approved by the FFA Signatories, or the activity is consistent with an applicable RMP pre-approved by the FFA Signatories. In a few specific areas, such as IR 7/18 in Parcel B, the Building 123 area in Parcel B, and the former landfill in Parcel E-2, it is expected that there will be special restrictions associated with protecting the integrity of waste containment structures or ongoing treatment systems and with implementing the operation and maintenance plan for those remedies. For parcels subject to early transfer under a FOSET, the restrictions may be more severe until cleanup actions are completed, but restrictions are still expected to be imposed at most or all areas after remediation is complete because the ubiquitous nature of low levels of hazardous materials in Bay Fill makes it infeasible to remediate all of those materials. The specific mechanisms used to implement and enforce the activity restrictions in the covenant and deed(s) will be set forth in a Land Use Control Remedial Design document approved by the FFA Signatories.

If the Navy transfers property under a lease or LIFOC, as explained previously, under CERCLA, the terms of the lease or LIFOC would contain restrictions similar to those described above that would be contained in a Covenant and deed under an early transfer. Although these restrictions will be imposed independent of this EIR through separate environmental regulatory processes, to ensure compliance with these restrictions prior to development activities that disturb soil or groundwater, mitigation measure MM HZ-1b would require SFDPH to verify, before all development activities at HPS Phase II that disturb soil or groundwater occur that the activities would be done in compliance with all applicable restrictions imposed pursuant to a CERCLA ROD, Petroleum Corrective Action Plan, FOST, FOSET or FOSL, or License Agreement, including restrictions imposed in deeds, covenants, leases, and LIFOCs, and requirements set forth in Land Use Control Remedial Design Documents, Risk Management Plans and health and safety plans.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-1 **Construction activities associated with the Project would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of soil and/or groundwater with known contaminants from historic uses. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Construction activities associated with the Project would involve extensive construction to accommodate new development within that area, as shown in Figure II-4 and in Table II-2 in Chapter II. Site preparation could include deep excavations for large structures such as residential towers; cut material may be used elsewhere within the Project site as fill, subject to certain restrictions; installation of foundation piles; trenching for utility lines; grading and compaction; and other earth-disturbing activities. Those activities could result in exposure to known contaminants at the Project site that could expose construction workers, the public, or the environment to hazardous materials. Implementation of mitigation measure MM HZ-1a would reduce effects related to exposure of known contaminants at Candlestick Point, including construction activities at CPSRA, by requiring compliance with Article 22A or an equivalent process. For construction activities at HPS Phase II, mitigation measure MM HZ-1b would require SFDPH to verify, before all development activities at HPS Phase II that disturb soil or groundwater occur, that the activities would be done in compliance with all applicable restrictions imposed for the site by requiring compliance

with additional Article 31 sections for specific parcels or an equivalent process. Implementation of these measures would ensure that potential adverse effects on human health and the environment from exposure to known subsurface hazards from construction activities would be reduced to a less-than-significant level.

Impact HZ-2: Exposure to Previously Unidentified Contaminants During Construction

Impact of Candlestick Point

Impact HZ-2a **Construction at Candlestick Point would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of soil and/or groundwater with previously unidentified subsurface contaminants from historic uses. (Less than Significant with Mitigation) *[Criterion K.b]***

As at any development in an urban setting, particularly one to be constructed on Bay Fill, there is a potential for construction activities at Candlestick Point to encounter previously unidentified hazards, such as an abandoned underground storage tank located before permitting requirements were imposed, or other hazards. Exposure of construction workers, the public, or the environment to such hazards could result in a significant impact. The purpose of Article 22A is to minimize this potential at construction sites on Bay Fill, by requiring a site evaluation and soil sampling. If the results of the evaluation and testing indicate hazardous wastes are present in soil, site mitigation measures must be identified and a site mitigation report submitted to SFDPH, prior to commencement of construction activities. Nevertheless, there is still some potential that unidentified hazardous material releases could be encountered after compliance with the Article 22A process. For example, if an unidentified UST were discovered during construction activities, it would have to be closed in place or removed. Removal activities could pose both health and safety risks, such as the exposure of workers, tank handling personnel, and the public to tank contents or vapors. Similarly, the discovery of buried debris that could be hazardous could also present an increased risk of adverse health or environmental effects.

The likelihood that significant adverse effects would result from the discovery of previously unidentified USTs is minimal because there are multiple existing requirements in place to address such effects, such as Article 22A, RWQCB, and SFDPH UST removal and site cleanup requirements, implementation of contingency monitoring procedures and RWQCB notification (as necessary), and implementation of a site-specific health and safety plan (HASP) prepared in accordance with Cal/OSHA regulations.

To reduce impacts related to exposure to unknown contaminants at Candlestick Point, the following mitigation measure shall be implemented.

MM HZ-2a.1 *Unknown Contaminant Contingency Plan. (Applies to Candlestick Point, HPS Phase II, and off-site improvements.) Prior to obtaining the first site, building or other permit for development activities involving subsurface disturbance, the Project Applicant shall prepare and the San Francisco Department of Public Health shall approve a contingency plan to address unknown contaminants encountered during development activities. This plan, the conditions of which shall be incorporated into the first permit and any applicable permit thereafter, shall establish and describe procedures for implementing a contingency plan, including appropriate notification to nearby property owners, schools, and residents and appropriate site control procedures, in the event unanticipated subsurface hazards or hazardous material releases are*

discovered during construction. Control procedures would include, but would not be limited to, further investigation and, if necessary remediation of such hazards or releases, including off-site removal and disposal, containment or treatment. In the event unanticipated subsurface hazards or hazardous material releases are discovered during construction, the requirements of this unknown contaminant contingency plan shall be followed. The contingency plan shall be amended, as necessary, in the event new information becomes available that could affect the implementation of the plan. This measure shall be implemented for HPS Phase II through additions to Article 31 or through an equivalent process established by the City or Agency as explained in MM HZ-1b.

MM HZ-2a.2 *Site-Specific Health and Safety Plans. (Applies to Candlestick Point, HPS Phase II, and off-site improvements.) Prior to obtaining the first site, building or other permit for the Project from the City for development activities involving subsurface disturbance, the Project Applicant shall prepare and submit to SFDPH a site-specific health and safety plan (HASP) in compliance with applicable federal and state OSHA requirements and other applicable laws to minimize impacts to public health and the environment. Implementation of the plan shall be required as a condition of any applicable permit. The plan shall include identification of chemicals of concern, potential hazards, personal protective equipment and devices, and emergency response procedures. The HASP shall be amended, as necessary, in the event new information becomes available that could affect the implementation of the plan.*

This measure shall be implemented for HPS Phase II through additions to Article 31 or through an equivalent process established by the City or Agency as explained in MM HZ-1b.

Implementation of mitigation measure MM HZ-2a.1 would require the development of an unknown contaminant contingency plan to describe procedures to follow in the event unexpected contamination is encountered during construction activities, including procedures for ensuring compliance with the above laws and regulations. Additionally, mitigation measure MM HZ-2a.2, would require the preparation and implementation of a site-specific HASP in compliance with federal and state OSHA regulations and other applicable laws. Implementation of those measures would ensure that potential adverse effects on human health and the environment from unidentified subsurface hazards would be reduced to a less-than-significant level.

Impact of Hunters Point Shipyard Phase II

Impact HZ-2b **Construction at HPS Phase II would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of soil and/or groundwater with previously unidentified subsurface contaminants from historic uses. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

As noted in the Setting, there have been a number of investigations and actions to identify and remove subsurface structures (e.g., USTs, utility lines) at HPS Phase II and to manage identified contamination from those historic uses. Although these efforts have been extensive, the potential still exists for unidentified, old, or abandoned subsurface structures to be present at sites to be developed in HPS Phase II; in particular, it has not always been feasible to conduct physical investigation or comprehensive soil testing to determine the presence of USTs or the extent, if any, of soil contamination underneath existing buildings and structures.

If an unidentified UST were discovered during construction activities, it would have to be closed in place or removed. Removal activities could pose both health and safety risks, such as the exposure of workers, tank handling personnel, and the public to tank contents or vapors. Similarly, the discovery of buried debris that could be hazardous could also present an increased risk of adverse health or environmental effects. The likelihood that significant adverse effects from the discovery of previously unidentified USTs would occur is minimal because there are multiple existing requirements in place to address such effects, such as the RWQCB's requirement to prepare and implement parcel-by-parcel CAPs comprehensively addressing petroleum issues, and the SFDPH UST removal and site cleanup requirements, implementation of contingency monitoring procedures and RWQCB notification (as necessary).

Implementation of mitigation measure MM HZ-2a.1 would require the development of an unknown contaminant contingency plan to describe procedures to follow in the event unexpected contamination is encountered during construction activities, including procedures for ensuring compliance with the above laws and regulations, in conjunction with implementation of mitigation measure MM HZ-2a.2, which would require the preparation of a site-specific HASP prepared in accordance with federal and state OSHA and other applicable regulations. Implementation of those measures would ensure that potential adverse effects on human health and the environment from unidentified subsurface hazards would be reduced to a less-than-significant level.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-2 **Construction activities associated with the Project would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of soil and/or groundwater with previously unidentified subsurface contaminants from historic uses. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

As at any development in an urban setting, particularly one to be constructed on Bay Fill, there is a potential for construction activities associated with the Project to encounter previously unidentified hazards, such as an abandoned underground storage tank located before permitting requirements were imposed, or other hazards. Exposure of construction workers, the public, or the environment to such hazards could result in a significant impact. Implementation of mitigation measures MM HZ-2a.1 would require the development of an unknown contaminants contingency plan. Mitigation measure MM HZ-2a.2 would require the preparation and implementation of a site-specific health and safety plan. Implementation of mitigation measures MM HZ-2a.1 and MM HZ-2a.2 would ensure that potential adverse effects on human health and the environment from unidentified subsurface hazards would be reduced to a less-than-significant level.

Impact HZ-3: Off-Site Transport and Disposal of Contaminated Soil and Groundwater

Impact of Candlestick Point

Impact HZ-3a **Construction at Candlestick Point would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of off-site transport and disposal of contaminated soil and groundwater. (Less than Significant with Mitigation) *[Criterion K.b]***

For those locations within Candlestick Point where remediation or UST removal could require off-site transport of contaminated soil or groundwater, exposure to hazardous materials could result if these materials were not handled appropriately during transport or disposal. These materials could be classified as a hazardous waste under federal or state regulations depending on the specific characteristics of the materials. The generator of the hazardous wastes would be required to follow federal or state regulations for characterization of and manifesting of the wastes, using licensed hazardous waste haulers, and disposing the materials at an appropriately permitted disposal or recycling facility. Soil or groundwater containing petroleum and other chemical products that do not meet the regulatory definition of hazardous waste would still be subject to special disposal requirements under RWQCB regulations and solid waste laws. These measures are described under Impact HY-1a in Section III.M. To reduce potential impacts of groundwater discharge to separate stormwater systems, mitigation measure MM HY-1a.3 would require the Project Applicant to prepare and implement a dewatering plan and comply with applicable standards to protect receiving water quality and anticipated SFPUC and/or RWQCB permit compliance provisions.

In addition, if construction in Candlestick Point would require dewatering of groundwater, a release of hazardous materials could occur, potentially resulting in exposure to the public and the environment. If dewatering were required, the groundwater could be discharged to the City's combined storm and sanitary sewer system in compliance with the Industrial Waste Ordinance, *Public Works Code*, Article 4.1, and Order No. 158170 of the DPW (refer to Section III.M for a discussion of Article 4.1 and Order No. 158170 and with SFPUC discharge guidelines). These regulations require a permit for discharge to the combined sewer, sampling of the water to be discharged and establish discharge limitations and other discharge criteria. Article 4.1 also prohibits discharge of hazardous wastes into the Combined Sewer System.

Under the Industrial Waste Ordinance, the discharged water would need to be sampled prior to and possibly during dewatering (depending on permit conditions) to demonstrate that discharge limitations in the ordinance were met. If the pumped groundwater would not meet discharge requirements, on-site pretreatment may be required before discharge to the sewer system. If standards could not be met with on-site treatment, the SFPUC may allow the discharger to pay a premium to discharge the wastewater to the system, or the discharger may need to transport the wastewater off site using a certified waste hauler. Thus, compliance with the Industrial Waste Ordinance and mitigation measure MM HY-1a.3 would ensure that potential adverse effects on human health and the environment from discharge of contaminated water to the sewer system would be reduced to a less-than-significant level.

Impact of Hunters Point Shipyard Phase II

Impact HZ-3b **Construction at HPS Phase II would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of off-site transport and disposal of contaminated soil and groundwater. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Construction activities in HPS Phase II could involve extensive construction to accommodate new development. Site preparation could include deep excavations for large structures such as residential towers; cut material may be used elsewhere as fill, subject to certain restrictions; installation of foundation piles; trenching for utility lines; grading and compaction; and other earth-disturbing activities. To the extent that the property under development contains hazardous materials at the time of development, some soils may need to be removed and disposed of off site.

For those locations within HPS Phase II where construction would require off-site transport of contaminated soil, the remediation contractor would be required, as necessary and where required, to follow state and federal regulations for manifesting (including transportation and disposal) the wastes, using licensed hazardous waste haulers, and disposing the materials at a permitted disposal or recycling facility. The ICs and, if applicable, Risk Management Plans, would set forth the process for approval or specific approved methods for disposal of excavated soils during grading or removal of groundwater during dewatering.

Likewise, the ICs and, if applicable, Risk Management Plans would establish a process for regulatory agency approval that will describe the procedure that must be followed to ensure that extraction of groundwater that may be necessary to accommodate trenching for utilities would not alter the physical or chemical characteristics of contaminant plumes. If dewatering were required, the groundwater could be discharged to the City's combined storm and sanitary sewer system provided the discharged water complied with the Industrial Waste Ordinance, *Public Works Code*, Article 4.1, and Order No. 158170 of the DPW (refer to Section III.M for a discussion of Article 4.1 and Order No. 158170 and with SFPUC discharge guidelines). The discharged water may be required to be sampled both prior to and during dewatering to demonstrate that discharge limitations in the ordinance are met. If the pumped groundwater would not meet discharge requirements, on-site pretreatment would be required before discharge to the sewer system. If standards could not be met with on-site treatment, the SFPUC may allow the discharger to pay a premium to discharge the wastewater to the system, or the discharger may need to transport the wastewater off site using a certified waste hauler. In addition mitigation measure MM HY-1a.3 would require the Project Applicant to prepare and implement a dewatering plan and comply with applicable standards to protect receiving water quality and anticipated RWQCB permit compliance provisions. Thus, compliance with the ICs and, if applicable, Risk Management Plans, the Industrial Waste Ordinance, and implementation of MM HZ-1b and would ensure that potential adverse effects on human health and the environment from disposal of dewatered groundwater would be reduced to a less-than-significant level.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-3 **Construction activities associated with the Project would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of off-site transport and disposal of contaminated soil and groundwater. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Construction associated with the Project where remediation activities would require off-site transport of contaminated soil or groundwater, exposure to hazardous materials could result if these materials were not handled appropriately during transport or disposal. At HPS Phase II, the ICs and, if applicable, Risk Management Plans, would set forth the process for approval or specific approved methods for disposal of excavated soils during grading or removal of groundwater during dewatering. For all construction and remediation activities associated with the Project requiring transport of contaminated soil or groundwater, compliance with existing federal, state, and local regulations and implementation of mitigation measures MM HZ-1b and MM HY-1a.3 would ensure that potential adverse effects on human health and the environment from disposal of dewatered groundwater would be reduced to a less-than-significant level.

Impact HZ-4: Installation of Underground Utilities

Impact of Candlestick Point

Impact HZ-4a **Construction at Candlestick Point would not expose construction workers, the public, or the environment to unacceptable levels hazardous materials as a result of improvements to existing and installation of new underground utilities. (Less than Significant with Mitigation) *[Criterion K.b]***

Development in Candlestick Point would involve the improvement of underground utilities as well as the installation of new utilities. There is the potential to encounter hazardous materials in soil and/or groundwater during work on underground utilities that, if encountered, could potentially expose workers or the environment to hazardous materials. Utility trenches have the potential to create a horizontal conduit for chemical contaminants contained in soil vapors or shallow groundwater to migrate along permeable soils that would be placed as trench backfill. In the event hazardous materials are encountered, the Agency would require the construction contractor to follow proper health and safety precautions and to dispose of contaminated soil and groundwater safely and legally, as discussed above. Installation of utilities bayward of the 1851 high-tide line would also be subject to the requirements of Article 22A. The potential for contaminants to be encountered is addressed by the requirement in mitigation measure MM HZ-2a.1 to prepare an unknown contaminant contingency plan. If contaminants were encountered in a location where piles are to be installed, the site mitigation plan required by Article 22A and mitigation measure MM HZ-1a would specify procedures necessary to prevent pile installation from creating a vertical conduit for chemicals occurring in shallow groundwater to move along the pile to deeper groundwater zones, and avoid degradation of the deeper groundwater. The measure would require all excess fill or native soil materials generated during pile driving to be properly managed. Implementation of mitigation measures MM HZ-1a and MM HZ-2a.1 would ensure the safe handling of potentially contaminated materials encountered during improvement or installation of underground utilities and effects on human health and the environment would be reduced to a less-than-significant level.

Impact of Hunters Point Shipyard Phase II

Impact HZ-4b **Construction at HPS Phase II would not expose construction workers, the public, or the environment to unacceptable levels hazardous materials as a result of improvements to existing and installation of new underground utilities. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Development in HPS Phase II would involve the improvement of underground utilities to serve new development. As described above for Candlestick Point, utility trenches have the potential to create a horizontal conduit for chemical contaminants contained in soil vapors or shallow groundwater to migrate along the permeable soils that would be placed as trench backfill. The areas of the site that require vapor or groundwater utility cutoffs and the performance standard for these systems will be identified in the remedial design documents that must be prepared under the CERCLA process before these activities can be carried out. Compliance with the ICs and any applicable RMPs, and implementation of mitigation measures MM HZ-1b, MM HZ-2a.1, and MM HZ-2a.2 would avoid or minimize the potential for horizontal migration of contaminants in HPS Phase II, which would reduce effects to less-than-significant levels. Underground utility construction off site, or in portions of HPS Phase II retained by the Navy to support development of the Project in areas the Navy has transferred, is discussed in Impact HZ-11. Those measures would ensure the safe handling of potentially contaminated materials encountered during improvement or installation of underground utilities and effects on human health and the environment would be reduced to a less-than-significant level.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-4 **Construction activities associated with the Project would not expose construction workers, the public, or the environment to unacceptable levels hazardous materials as a result of improvements to existing and installation of new underground utilities. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Construction of the Project would involve the improvement of underground utilities as well as the installation of new utilities. There is the potential to encounter hazardous materials in soil and/or groundwater during work on underground utilities that, if encountered, could potentially expose workers, the public, or the environment to hazardous materials. Implementation of mitigation measure MM HZ-1a, MM HZ-1b, MM HZ-2a.1, and MM HZ-2a.2 would ensure the safe handling of potentially contaminated materials encountered during improvement or installation of underground utilities and effects on human health and the environment would be reduced to a less-than-significant level.

Impact HZ-5: Installation of Foundation Support Piles

Impact of Candlestick Point

Impact HZ-5a **Construction at Candlestick Point would not create vertical conduits for hazardous materials that could contaminate groundwater as a result of installation of foundation support piles. (Less than Significant with Mitigation) *[Criterion K.b]***

Candlestick Point is principally underlain by fill materials that overlie a thick sequence of Bay Mud (refer to Section III.L). Additional clay units and bedrock underlie the Bay Mud. Foundation support piles would be driven from the surface to various depths within Candlestick Point to provide structural support for various building and structure features. Unless properly managed and depending on the depth and location of the support piles, shallow groundwater could be encountered as a result of this activity. Groundwater generation is not a concern when driving piles. Piles installed in locations where contaminants have been identified could, under certain soil conditions, create a vertical conduit for chemicals occurring in shallow groundwater to move along the pile to deeper groundwater zones, causing degradation of the deeper groundwater, a potentially significant impact.

Piles installed at Candlestick Point generally would extend through the Young Bay Mud to develop friction support in the underlying Old Bay Clay. In certain locations, the piles could extend through the Old Bay Clay to develop end support by resting on the bedrock that underlies the Project site. Prior to installing each pile, a pilot borehole would be drilled through the artificial fill to ensure the pile would pass undamaged and properly aligned through the debris and rubble that commonly is encountered in non-engineered fill materials. Drilling the pilot boreholes also would reduce the potential for the piles to push artificial fill that may contain hazardous constituents into the underlying sediments or groundwater, as could occur if the piles were driven from the ground surface without the benefit of pre-drilling. Mitigation measure MM HZ-5a would require pre-drilling pilot boreholes before pile driving in non-engineered fill material to avoid potential contaminant transport.

Because Bay Mud is soft, cohesive, and has a low permeability, the materials encountered during pile installation would adhere to the sides of piles during and after placement. This action would form a seal that would effectively prevent the formation of conduits for shallow groundwater to migrate downward into deeper water-bearing zones. Therefore, natural conditions would prevent the creation of a vertical conduit for chemicals moving from shallow intervals to deeper ones, or vice versa.

To reduce impacts related to potential groundwater contamination resulting from installation of foundation support piles at Candlestick Point, the following mitigation measure shall be implemented.

MM HZ-5a *Foundation Support Piles Installation Plan. (Applies to Candlestick Point and HPS Phase II.) Prior to obtaining a permit from the City that authorizes installation of deep foundation piles, the Project Applicant shall prepare and submit a plan acceptable to the City stating that pilot boreholes for each pile would be drilled through the artificial fill materials so the piles can be installed without damage or misalignment and to prevent potentially contaminated fill materials from being pushed into the underlying sediments or groundwater. This measure shall be implemented for Candlestick Point through implementation of mitigation measure MM HZ-1a. This measure shall be implemented for HPS Phase II through additions to Article 31 or through an equivalent process established by the City or Agency as explained in MM HZ-1b.*

Implementation of mitigation measure MM HZ-5a would reduce potential groundwater quality impacts from pile driving to less-than-significant levels by ensuring compliance with Articles 22A and 31 and preparation of a plan for pilot boreholes for each pile to prevent disturbance of potentially contaminated fill materials.

Impact of Hunters Point Shipyard Phase II

Impact HZ-5b **Construction at HPS Phase II would not create vertical conduits for hazardous materials that could contaminate groundwater as a result of installation of foundation support piles. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

HPS Phase II is principally underlain by fill materials that overlie a thick sequence of Bay Mud (refer to Section III.L). If foundation support piles were used, shallow groundwater could be encountered during installation.

Piles installed in locations at HPS Phase II where contaminants have been identified could, under certain soil conditions, create a vertical conduit for chemicals occurring in shallow groundwater to move along the pile to deeper groundwater zones, causing degradation of the deeper groundwater. Piles generally would extend through the Young Bay Mud to develop friction support in the underlying Old Bay Clay. In certain locations, the piles could extend through the Old Bay Clay to develop end support by resting on the bedrock that underlies the Project site. Prior to installing each pile, a pilot borehole would be drilled through the artificial fill to ensure the pile would pass undamaged and properly aligned through the debris and rubble that commonly is encountered in non-engineered fill materials. Drilling the pilot boreholes also would reduce the potential for the piles to push artificial fill that may contain hazardous constituents into the underlying sediments or groundwater, as could occur if the piles were driven from the ground surface without the benefit of pre-drilling. Mitigation measure MM HZ-5a would require pre-drilling pilot boreholes before pile driving in non-engineered fill material to avoid potential contaminant transport.

Restrictions that will apply upon transfer will dictate where pile driving will be permitted and under what circumstances. If permitted, all excess fill or native soil materials generated during pile driving would need to be managed consistent with the restrictions set forth in the ICs and any applicable Risk Management Plans as described above. Compliance with those restrictions through mitigation measures MM HZ-1b and MM HZ-5a would reduce potential groundwater quality impacts from pile driving to less-than significant levels.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-5 **Construction activities associated with the Project would not create vertical conduits for hazardous materials that could contaminate groundwater as a result of installation of foundation support piles. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

The Project site is principally underlain by fill materials that overlie a thick sequence of Bay Mud (refer to Section III.L). Additional clay units and bedrock underlie the Bay Mud. Foundation support piles would be driven from the surface to various depths within the Project site to provide structural support for various building and structure features. Unless properly managed and depending on the depth and location of the

support piles, shallow groundwater could be encountered as a result of this activity. Groundwater generation is not a concern when driving piles. Piles installed in locations where contaminants have been identified could, under certain soil conditions, create a vertical conduit for chemicals occurring in shallow groundwater to move along the pile to deeper groundwater zones, causing degradation of the deeper groundwater, a potentially significant impact. Implementation of mitigation measures MM HZ-1a, MM HZ-1b, and MM HZ-5a would reduce potential groundwater quality impacts from pile driving to less-than significant levels.

Impact HZ-6: Soil Handling, Stockpiling, and Transport Within the Project Site Boundaries

Impact of Candlestick Point

Impact HZ-6a **Construction at Candlestick Point would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of handling, stockpiling, and transport of soil that may contain contaminants. (Less than Significant with Mitigation) *[Criterion K.b]***

Various construction activities in Candlestick Point, such as grading, trenching, compacting, and excavating soils, would result in soil being handled and moved. The excavated soil is expected to be used as fill elsewhere at Candlestick Point and possibly at HPS Phase II. Movement of soil that contains hazardous materials could result in impacts from human exposure to chemicals in the soil from dust and impacts to water quality and the environment if hazardous constituents were to migrate to the Bay. Movement of these soils also could result in impacts to air quality and water quality from the release of particulate matter to the air or sediment in storm water. Potential impacts from stockpiling and transport of these soils and associated dust control and stormwater management mitigation measures are discussed in greater detail in Section III.H (Air Quality) and Section III.M (Hydrology and Water Quality). Potential impacts associated with sediment that could be disturbed during shoreline improvements are evaluated in Impact HZ-10a

Soil excavated from portions of Candlestick Point that are subject to Article 22A and mitigation measure MM HZ-1a would be subject to restrictions or requirements imposed on soil movement or reuse within the Project site as part of any applicable site mitigation plan. Soil characterized as hazardous waste would be subject to applicable hazardous waste management, transportation, and disposal requirements under federal and state hazardous waste management laws. Transportation and reuse of soils not characterized as hazardous waste would be conducted in accordance with any applicable laws concerning nonhazardous soil transport and disposal.

Soil excavated from Candlestick Point could be transported to and reused at HPS Phase II only if (1) the soil were not characterized as hazardous waste under state or federal hazardous waste management regulations; and (2) the soil were to comply with any applicable soil import requirements related to what type of soil can be placed into particular areas of the site, imposed as part of the remediation program overseen by the FFA Signatories and/or by a RMP and/or by local ordinance. In the case of soils containing hazardous waste at Candlestick Point, the site mitigation plan would incorporate dust control measures, including placing covers on the trucks to reduce the potential for spreading material from one area to another or requiring that soil be sufficiently moist to prevent dust generation during transport. Further, whenever workers could be exposed to hazardous levels of chemicals, a site-specific HASP would

be prepared by the contractor prior to construction and would contain a section regarding decontamination of both personnel and equipment. The site mitigation plan would also address the potential for trespassers or visitors to gain access to construction sites and come into direct contact with native soils by specifying measures to prevent unauthorized entry into the construction site and provide appropriate monitoring/enforcement procedures to ensure the effectiveness of site security.

Soil handling, stockpiling, and transport activities have the potential to create erosion and potential migration of soils into the Bay during rainstorms, absent implementation of management measures. Soils could contain contaminants such as metals and organic compounds, which could degrade water quality in the Bay. Implementation of measures to control stormwater runoff during construction would also control discharge of potential chemicals adhered to soil in the runoff. These measures are described under Impact HY-1a in Section III.M and include implementation of a Stormwater Pollution Prevention Plan (SWPPP) and best management practices (BMPs) for construction sites. Mitigation measures MM HY-1a.1 and MM HY-1a.2 would require preparation of a SWPPP to identify the specific measures and BMPs that are applicable to Candlestick Point construction activities in the event of a spill or exposure of hazardous materials.

Compliance with the procedures described above would ensure that soil handling, stockpiling, and movement within Candlestick Point would not present a significant risk to human health and the environment, and would also reduce the potential for inadvertent exposure of adults and children to contaminated soils. Therefore, with implementation of Article 22A, mitigation measures MM HZ-1a, MM HY-1a.1, and MM HY-1a.2, impacts related to handling, stockpiling, and transport of contaminated soil would be reduced to less-than-significant levels.

Impact of Hunters Point Shipyard Phase II

Impact HZ-6b **Construction at HPS Phase II would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of handling, stockpiling, and transport of soil that may contain contaminants. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Various construction activities at HPS Phase II, such as grading, trenching, compacting, and excavating, would result in soil being handled and moved. The excavated soil may be used as fill elsewhere at HPS Phase II, to the extent permissible under the restrictions discussed below, but would not be reused at CPSRA or any other off-site locations. Movement of soil that contains hazardous materials could result in impacts from human exposure to chemicals in the soil from dust and impacts to water quality and the environment if hazardous constituents were to migrate to the Bay. Movement of nonhazardous soils also could result in impacts to air quality and water quality from the release of particulate matter to the air or sediment in storm water. Potential impacts from stockpiling and transport of nonhazardous soils and associated dust control and stormwater management mitigation measures are discussed in greater detail in Section III.H (Air Quality) and Section III.M (Hydrology and Water Quality). Potential impacts associated with sediment that could be disturbed during shoreline improvements are evaluated in Impact HZ-10b.

Restrictions on handling, stockpiling and transport of soil during construction activities at HPS Phase II will be a component of the legally-enforceable restrictions on uses and activities at the Project site described above (refer to the "Management of Hazardous Materials Contamination Risks During Development" section) which the Navy, USEPA, DTSC, RWQCB, and CDPH will, independent of the Project and this

EIR, require be in place before any Project development activity occurs at HPS Phase II. Although these restrictions will be imposed independent of this EIR through independent environmental regulatory processes, to ensure compliance with these restrictions prior to development activities, mitigation measure MM HZ-1b would require SFDPH to verify, before any development activity at HPS Phase II occurs, that it would be done in compliance with all restrictions imposed pursuant to a CERCLA ROD, Petroleum Corrective Action Plan, FOST, FOSET or FOSL, or License Agreement, including restrictions imposed in deeds, covenants, leases, and LIFOCs, and requirements set forth in Land Use Control Remedial Design Documents, Risk Management Plans, and health and safety plans. Those legally enforceable restrictions would incorporate dust control measures such as covers on the trucks to reduce the potential for spreading material from one area to another or requiring that soil be sufficiently moist to prevent dust generation during transport. Further, whenever workers could be exposed to hazardous levels of chemicals, a site-specific HASP would be prepared by the contractor prior to construction and would contain a section regarding decontamination of both personnel and equipment. The restrictions would also address the potential for trespassers or visitors to gain access to construction sites and come into direct contact with contaminated soils by specifying measures to prevent unauthorized entry into the construction site and provide appropriate monitoring/enforcement procedures to ensure the effectiveness of site security.

Those legally enforceable restrictions would incorporate dust control measures such as covers on the trucks to reduce the potential for spreading material from one area to another or requiring that soil be sufficiently moist to prevent dust generation during transport. Further, whenever workers could be exposed to hazardous levels of chemicals, a site-specific HASP would be prepared by the contractor prior to construction and would contain a section regarding decontamination of both personnel and equipment. The restrictions would also address the potential for trespassers or visitors to gain access to construction sites and come into direct contact with contaminated soils by specifying measures to prevent unauthorized entry into the construction site and provide appropriate monitoring/enforcement procedures to ensure the effectiveness of site security.

Soil handling, stockpiling, and transport activities have the potential to create erosion and potential migration of soils into the Bay during rainstorms, absent implementation of management measures. Soils could contain contaminants such as metals and organic compounds, which could degrade water quality in the Bay. Implementation of measures to control stormwater runoff during construction would also control discharge of potential chemicals adhered to soil in the runoff. Mitigation measures MM HY-1a.1 and MM HY-1a.2 would require preparation of a SWPPP would be required to identify the specific measures and BMPs that are applicable to HPS Phase II construction activities in the event of a spill of construction materials or exposure of hazardous materials. The SWPPP would identify the specific measures that are applicable to HPS Phase II construction.

As a result of these controls and mitigation measures, including mitigation measures MM HZ-1b, MM HY-1a.1, and MM HY-1a.2, impacts related to handling, stockpiling, and transport of contaminated soil would be reduced to less-than-significant levels.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-6 **Construction activities associated with the Project would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the handling, stockpiling, and transport of soil that may contain contaminants. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Project construction activities, such as grading, trenching, compacting, and excavating, would result in soil being handled and moved. The excavated soil is expected to be used as fill elsewhere at within the Project site. Handling, stockpiling, and transport of soil that contains hazardous materials could result in impacts from human exposure to chemicals in the soil from dust and impacts to water quality and the environment if hazardous constituents were to migrate to the Bay. For all construction associated with the Project requiring handling, stockpiling, or transport of soil, compliance with existing federal, state, and local regulations and controls and implementation of mitigation measures MM HZ-1a, MM HZ-1b, MM HY-1a.1, and MM HY-1a.2 would ensure that potential adverse effects on human health and the environment would be reduced to a less-than-significant level.

Impact HZ-7: Contaminated Surface Runoff from Construction Sites

Impact of Candlestick Point

Impact HZ-7a **Construction at Candlestick Point would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials that could be present in stormwater runoff. (Less than Significant with Mitigation) *[Criterion K.b]***

Construction activities at Candlestick Point, such as the compaction and installation of fill, grading, and other geotechnical work have the potential to remove the vegetative cover from parts of the site, spill soils onto roads, or otherwise create the potential for erosion or movement of soils from the Project site and potentially into surface waters during rain storms, absent implementation of management measures. Implementation of measures to control stormwater runoff during construction would also control potential discharge of chemicals, if chemicals were present in the runoff. These measures are described under Impact HY-1a in Section III.M and include implementation of a SWPPP and BMPs for construction sites. Mitigation measures MM HY-1a.1 and MM HY-1a.2 would require preparation of a SWPPP to identify the specific measures and BMPs that are applicable to Candlestick Point construction activities in the event of a spill or exposure of hazardous materials.

The actual control measure(s) that would be implemented would be developed to account for the specific characteristics of each site, contaminant type and concentrations, potential exposure pathways, and populations that could be at risk. Implementation of these measures, which would be identified in a site-specific SWPPP, would be adequate to control human health and environmental exposure from unremediated, if any, soil and/or groundwater sites that are unknown but may be encountered during construction at Candlestick Point. The types of actions likely to be required by a site mitigation plan and unknown contaminant contingency plan are included in mitigation measures MM HZ-1a and MM HZ-2a.1. Therefore, there would not be a significant hazard to the public or the environment involving release of contaminated surface runoff into the environment. Implementation of mitigation

measures MM HZ-1a, MM HZ-2a.1, MM HY-1a.1, and MM HY-1a.2 would ensure that potential adverse effects on human health and the environment would be reduced to a less-than-significant level.

Impact of Hunters Point Shipyard Phase II

Impact HZ-7b **Construction at HPS Phase II would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials that could be present in stormwater runoff. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Construction activities at HPS Phase II, such as the compaction and installation of fill, grading, and other geotechnical work have the potential to remove the vegetative cover from parts of the site, spill soils onto roads, or otherwise create the potential for erosion or movement of soils from the Project site and potentially into surface waters during rain storms, absent implementation of management measures. Implementation of measures to control stormwater runoff during construction would also control discharge of potential chemicals if present in the runoff. Mitigation measures MM HY-1a.1 and MM HY-1a.2 would require preparation of a SWPPP to identify the specific measures and BMPs that are applicable to HPS Phase II construction activities in the event of a spill of construction materials or exposure of hazardous materials. The SWPPP would identify the specific measures that are applicable to HPS Phase II construction.

The actual control measure(s) that would be implemented would be developed to account for the specific characteristics of each site, contaminant type and concentrations, potential exposure pathways, and populations that could be at risk. Implementation of these measures, which would be identified in a site-specific SWPPP, would be adequate to control human health and environmental exposure from unremediated, if any, soil and/or groundwater sites that are unknown, but may be encountered during construction at HPS Phase II. Therefore, there would not be a significant hazard to the public or the environment involving release of contaminated surface runoff into the environment. Implementation of mitigation measures MM HY-1a.1, MM HY-1a.2, MM HZ-1b, and MM HZ-2a.1 would ensure that potential adverse effects on human health and the environment would be reduced to a less-than-significant level.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-7 **Construction activities associated with the Project would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials that could be present in stormwater runoff. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Project construction activities, such as the compaction and installation of fill, grading, and other geotechnical work have the potential to remove the vegetative cover from parts of the site, spill soils onto roads, or otherwise create the potential for erosion or movement of soils from the Project site and potentially into surface waters during rain storms, absent implementation of management measures. Mitigation measures MM HY-1a.1 and MM HY-1a.2 would require preparation of a SWPPP to identify the specific measures and BMPs that are applicable to construction activities in the event of a spill of construction materials or exposure of hazardous materials. Implementation of mitigation measures MM HZ-1a, MM HZ-1b, MM HZ-2a.1, MM HY-1a.1, and MM HY-1a.2 would ensure that potential adverse effects on human health and the environment would be reduced to a less-than-significant level.

Impact HZ-8: Exposure to Hazardous Materials Releases That Have Not Been Fully Remediated

Impact HZ-8 **Project occupants or visitors in or near portions of HPS Phase II where remediation has not been fully completed would not be exposed to unacceptable levels of hazardous materials. (Less than Significant with Mitigation)** ***[Criteria K.b and K.d]***

As presented in the Setting, the results of comprehensive basewide and parcel-specific investigations have shown that chemicals and radioactive materials are present in soil and groundwater in various locations throughout HPS Phase II at levels that require remediation. As described above in the "Overview of the Environmental Investigation and Cleanup Process" section, the Navy has completed substantial investigation and remediation of the site and the FFA Signatories overseeing the remediation program have required interim measures to be put in place in areas that still require remediation. This would ensure that while remediation continues, the site would not pose a risk to persons or the environment outside of the ongoing remediation locations. Those measures include numerous actions to remove hazardous materials from soil and groundwater at the site, cleaning up shoreline debris, placing a temporary cap on the landfill at Parcel E-2 and securing areas still undergoing remediation with fencing. The cleanup required by the regulatory agencies will continue to be implemented by the Navy regardless of whether or not the Project is implemented.

In addition to the numerous cleanup activities for more conventional contaminants that are complete, underway, or are planned for each parcel within HPS Phase II, the Navy has prioritized the removal of all radiologically contaminated soils throughout the entire HPS Phase II site. This includes removal of former utility lines and impacted soils. Completion of radiological remedial actions will occur on each parcel prior to transfer of that parcel to the Agency.

As described above, RODs for many of the parcels have either been completed or are planned for completion in late 2009. Nevertheless, the remediation design documents necessary to carry out full remediation have not been developed nor approved. Further, while remediation investigations have been undertaken and remedies for Parcels C, E, E-2, and F have been refined, RODs have not been approved. Therefore, full remediation of the entire HPS Phase II site is not anticipated until after commencement of Project-related construction activities on, and perhaps occupancy of, portions of HPS Phase II. As described under Regulatory Framework, above, property in HPS Phase II could be transferred or leased (or accessed for limited purposes under a license or easement) to the Agency in advance of complete cleanup in two ways: FOSET or FOSL/LIFOC. Further, property that is fully remediated could be transferred to the Agency under a FOST while the Navy continues with remediation activities on other parcels.

Two types of impacts could be associated with occupancy on or near portions of HPS Phase II where remediation has not been fully completed. First, persons who would be present in portions of HPS Phase II prior to its complete remediation could be exposed to risks from exposure to hazardous materials releases that have not been fully remediated. Second, remediation activities themselves (e.g., soil excavation and groundwater treatment) could occur simultaneously with nearby construction and occupancy of new structures located in nearby areas where remediation has been completed; if not properly managed, these remediation activities could result in occupants or visitors being exposed to hazardous materials exposed

or emitted during the remediation activities. Both potential impacts of occupancy on or near sites where remediation has not been fully completed are addressed in this section. As described below, the risk of either type impact is not substantial because of the physical characteristics and administrative controls already in place. Nevertheless, the analysis in this section conservatively assumes there could be some risk to occupants or visitors in or near portions of HPS Phase II where remediation has not been fully completed, although that risk would be small.

The risk of exposure to hazardous materials releases in areas where remediation has not been fully completed is small, for the following reasons. First, all buildings and parcels within HPS Phase II have been investigated for chemical and radiological contamination. Second, human health risk assessments have been prepared to determine which locations could present a risk, and to determine approaches to cleanup. Where hazards existed that posed an immediate risk, the Navy has either removed the contaminant(s) or restricted access to those locations. Third, Parcels B, C, D-1, D-2, UC-1, UC-2, and at least half of Parcels E and G are covered with buildings, pavement, or other solid surfaces that would limit the amount of exposed soil that could become mobilized by wind or water. Fourth, as the Navy continues the cleanup of HPS, risks from unremediated hazardous materials releases will be further reduced throughout Project development. The potential risk to future occupants, workers, and visitors to unremediated sites would decrease.

The small risk of occupants or visitors being exposed to hazardous materials released will be addressed by the restrictions required by Navy cleanup documents such as CERCLA RODs, Petroleum Corrective Action Plans, FOSTs, FOSETs, FOSLs, Land Use Control Remedial Design Documents, Risk Management Plans and health and safety plans and restrictions set forth in property transfer documents, such as deeds, covenants, easements, LIFOCs. and short-term leases.

The principal purpose of the restrictions imposed at sites transferred or leased prior to completion of cleanup activities, under a FOSET or FOSL, are to ensure that the unremediated hazardous material releases will not pose a risk to occupants or visitors. This is accomplished through use restrictions (e.g., restrictions against residences, schools, childcare centers), through activity restrictions (e.g., restrictions against disturbing soil), and through site security requirements (e.g., fencing and signs around excavation sites). The restrictions imposed in FOSETS or FOSLs, and also those imposed on properties where cleanup is determined to be complete under a FOST, are designed to protect not only occupants and visitors on the parcel itself, but also on nearby property. This is sometimes accomplished through conservatively establishing the boundaries of the area subject to restrictions, to include a "buffer zone" establishing a safe distance from the area that was remediated. Similarly, restrictions may be imposed to address the potential of migration from nearby parcels where remediation has not been fully completed. This is sometimes accomplished through an ongoing monitoring requirement to determine if a groundwater plume, or methane, from an adjacent area has migrated, or it may be accomplished through a requirement to install vapor barriers to prevent exposure from releases from the adjacent property.

Compliance with the restrictions in these documents, which is required by MM HZ--1b, would reduce the potential impact of exposure to hazardous materials releases to occupants and visitors on or near portions of HPS Phase II where remediation has not been fully completed to less than significant.

As indicated above, occupants or visitors at or near portions of HPS Phase II where remediation activities have not been fully completed could also be exposed to hazardous materials as a result of remediation activities themselves, if physical controls and administrative procedures are not in place to manage that risk. Such remediation activities could include excavation and transport of contaminated soils to an off-site treatment or disposal facility, in-situ treatment of soils (e.g., soil vapor extraction), or groundwater treatment (with chemicals) that could expose occupants and visitors to contaminated dusts, soil gases, and other contaminated material. Table III.K-2 (Remedial Actions, Potential Environmental Effects, and Methods to Reduce Effects) provides an overview of the types of remediation activities, potential human health, and environmental effects associated with each activity for each parcel, and the types of measures that EPA, DTSC, and the Regional Water Board will require the Navy to implement to control exposures from such activities to people in proximity to the activities.

As a result of the protective measures described in Table III.K-2 that the environmental regulators will require the Navy to implement, the potential impact to occupants or visitors on or near portions of HPS Phase II from exposure to hazardous materials exposed or emitted during remediation activities conducted by the Navy is less than significant.

To the extent this impact could still be potentially significant despite the Navy's implementation of these protective measures, it would be reduced to less than significant through implementation of Mitigation Measure MM HZ-1b, which requires compliance with restrictions in cleanup and transfer documents. The determinations of suitability for transfer or lease made in FOSETs, FOSTs, and FOSLs all take into account the potential for ongoing remediation activities to be conducted on the parcel (in the case of a FOSET or FOSL) or on a nearby parcel (in the case of a FOST) to impact occupants or visitors; if such a risk is identified, the FOSET, FOSL or FOST would impose restrictions to address the risk.

Potential impacts to occupants or visitors from remediation activities that may be conducted by or on behalf of the Agency or the Project Applicant are addressed by MM HZ-12, which requires compliance with all requirements incorporated into remedial design documents, work plans, health and safety plans, dust control plans, and any other document or plan required under the Administrative Order on Consent. This includes all restrictions imposed pursuant to a CERCLA ROD, Petroleum Corrective Action Plan, FOSET, including restrictions imposed in deeds, covenants, and requirements set forth in Land Use Control Remedial Design Documents, Risk Management Plans and health and safety plans.

Impact HZ-9: Exposure to Hazardous Materials in Conjunction with Limited Remediation Activities During Construction of the Yosemite Slough bridge

Impact HZ-9 **Construction at HPS Phase II would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of Yosemite Slough bridge construction. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

The Project would include construction of a bridge crossing the narrowest part of the South Basin portion of the Yosemite Slough to link Candlestick Point with HPS Phase II. The northern access point for the bridge would be at the edge of Parcel E and Parcel E-2, in an area where radiological contaminants are suspected to be present below the surface (refer to Figure III.K-1).

Table III.K-2 Remedial Actions, Potential Environmental Effects, and Methods to Reduce Effects

	Parcels in Which Remedial Action Could Occur						
Remedial Action	*B*	*C, UC-2*	*D (includes D-1, UC-1, and G)*	*E/ E-2*	*F*	*Potential Environmental Effects and Sources*	*Methods to Reduce Effects*
				SOIL REMEDIATION			
Removal							
Conventional Excavation/ Temporary Stockpiling	X	X	X	X	X	Air emissions; contact with soil; potential infiltration of contaminants to groundwater; contaminants carried in stormwater runoff; inadvertent spread of contamination	Air monitoring and engineering controls; health and safety plan; covering soil stockpiles; NPDES (National Pollutant Discharge Elimination System) stormwater SWPPP; site security
Dredging					X	Air emissions from dredging equipment; contact with sediments; remobilization or spread of contaminants into surface water	Air monitoring and engineering controls; coffer dams, barriers and liners; health and safety plan; NPDES SWPPP
After excavation or dredging, off-site treatment, and/or disposal	X	X	X	X	X	After excavation, truck traffic and associated noise, criteria air pollutant emissions; inadvertent spread of contamination	Selecting best truck route, dust control measures (freeboard and tarping), decontaminating equipment leaving site
On-Site Physical/Chemical Treatment							
Soil Vapor Extraction	X	X				Air emissions, noise	Comply with BAAQMD regulations for emissions source controls; air monitoring; use mufflers on equipment and/or enclosures; health and safety plan
Active Landfill Gas Control System				X		Vapors from methane extraction	Air monitoring; soil gas monitoring
Containment							
Soil Covers	X	X	X	X	X	Soil movement, placement, compaction—air emissions, noise	Air monitoring and engineering controls; health and safety plan; covering stockpiled sediments; NPDES stormwater SWPPP; federal and state permit/mitigations to protect aquatic resources; site security
Asphalt and Concrete Covers	X	X	X	X		Air emissions from asphalt, air emissions from heavy equipment	Air monitoring and engineering controls; health and safety plan; NPDES stormwater SWPPP; federal and state permit/mitigations to protect aquatic resources; site security
Maintained Landscaping	X	X	X	X		Subsurface irrigation maintenance	Adequate cover with clean fill

Table III.K-2 Remedial Actions, Potential Environmental Effects, and Methods to Reduce Effects

	Parcels in Which Remedial Action Could Occur						
Remedial Action	*B*	*C, UC-2*	*D (includes D-1, UC-1, and G)*	*E/ E-2*	*F*	*Potential Environmental Effects and Sources*	*Methods to Reduce Effects*
Shoreline Revetment	X	X		X	X	Construction of revetment – heavy equipment emissions, noise, visual, disturbance of shoreline aquatic systems	Air monitoring and engineering controls; health and safety plan; covering stockpiled sediments; NPDES stormwater SWPPP; federal and state permit/mitigations to protect aquatic resources; site security
Multilayer Cap	X (IR7/18)			X		Construction of cap – air emissions and noise from equipment, construction site runoff into Bay	Air monitoring and engineering controls; health and safety plan; covering soils; NPDES stormwater SWPPP; site security
Geosynthetic Cap	X (IR 7/18)			X		Construction of cap – air emissions and noise from equipment, construction site runoff into Bay	Air monitoring and engineering controls; health and safety plan; covering soils; NPDES stormwater SWPPP; site security
Backfilling	X	X	X	X	X	Dust emissions from placement of fill, air emissions from heavy equipment, construction site runoff into Bay	Air monitoring and engineering controls; health and safety plan; covering soils; NPDES stormwater SWPPP; site security
Cofferdam				X	X	Construction of coffer dam – air emissions and from equipment, visual, construction site runoff, disturbance of shoreline aquatic systems	Air monitoring and engineering controls; health and safety plan; covering stockpiled sediments; NPDES stormwater SWPPP; federal and state permit/mitigations to protect aquatic resources; site security
						GROUNDWATER REMEDIATION	
Monitoring	X	X	X	X		Water sampling would involve minimal physical disturbance	Health and safety plan; quality assurance plan
Monitored Natural Attenuation (passive)		X		X		Monitoring would involve collecting and analyzing groundwater samples, which would involve minimal physical disturbance	Health and safety plan; quality assurance plan
In-Situ Chemical Treatment	X	X	X	X		Transport of chemical products to site, operation and maintenance of pumps – air, noise emissions	Air monitoring and engineering controls; health and safety plan; compliance with state and local hazardous materials use/storage regulations; site security
Vapor Controls	X	X	X	X		Collection of vapors in enclosed spaces – inhalation hazard, possible explosion hazard	Groundwater Soil Vapor Extraction (SVE) program, monitoring, vapor barriers in buildings

SEDIMENT AND SURFACE WATER REMEDIATION							
Removal/Backfill					X	Dust emissions from excavation; noise and air emissions from heavy equipment; contact with sediment; potential for contaminated sediments to be carried in stormwater runoff to Bay; potential to affect aquatic resources	Air monitoring and engineering controls; health and safety plan; covering stockpiled sediments; NPDES stormwater SWPPP; federal and state permit/mitigations to protect aquatic resources; site security
Removal and Off-Site Disposal	X	X	X	X	X	Dust emissions from excavation; noise and air emissions from heavy equipment. After excavation, truck traffic and associated noise, criteria air pollutant emissions; inadvertent spread of contamination; contact with sediment	In addition to above, selecting best truck route, dust control measures (freeboard and tarping), decontaminating equipment leaving site
Armored Cap/Aquablok Cap					X	Construction of cap—air emissions and noise from equipment, potential for cap materials to be carried into surface water; permanent visual effect; potential to affect aquatic resources	Air monitoring and engineering controls; health and safety plan; NPDES stormwater SWPPP; federal and state permit/mitigations to protect aquatic resources; site security
In-Situ Stabilization					X	Emissions and noise from heavy equipment	Air monitoring and engineering controls; health and safety plan; NPDES stormwater SWPPP; federal and state permit/mitigations to protect aquatic resources; site security
Monitored Natural Recovery					X	Monitoring would involve collecting and analyzing sediment and water samples, which would involve minimal physical disturbance	Specified monitoring protocols.
Monitoring	X	X	X	X	X	Same as above	Same as above

SOURCE: Compiled by PBS&J from Navy HPS reports.

- It is expected that construction of the bridge would occur in the early phase of the Project, likely before the Navy completes remediation of Parcels E and E-2. This section describes the impacts that could occur under such a scenario due to the presence of radiological materials and the actions that would be taken to address the presence of radiological materials within the bridge construction area.

  If soil, sediment, or debris containing radiological contamination were disturbed, this could expose construction workers to hazards associated with radiological materials. The public and the environment could also be at risk if the excavated materials were not properly managed.

  To access the bridge construction site from HPS Phase II, excavation of the potentially radiologically contaminated area must first be completed. Before any work beings, a removal action workplan would be submitted to and approved by the FFA Signatories and the CDPH. The workplan would include the same types of safety protocols and control measures included in previously approved workplans for the Navy's ongoing excavations of the radiologically impacted sewer lines and storm drains throughout HPS. In addition, the area to be excavated (work corridor) would be established in conjunction with design work and identified in the work plan, and all construction documents would indicate the boundary of excavation work corridor. No excavation would take place outside that boundary.

  The safety protocols and control measures would include the following:

  - The contractor will implement radiological control program including set up of designated lay down areas, radiological control areas, and exclusion zones.
  - All personnel working on the site will receive specific training as required to perform the work specified.
  - The contractor will implement an erosion and stormwater management plan including installation of erosion and stormwater control measures.

  The approach to clearing the corridor to allow construction would involve excavating materials that would be tested for radiological materials as the soil is removed. As noted above, only soils within the corridor boundary would be excavated and tested. To accomplish this, the contractor would mobilize radiological sorting equipment and all other construction vehicles and equipment to the site required to execute the Project. Pilot tests would be performed to calibrate the equipment that ensure the sorting process is working properly and the contractor is achieving the required screening levels. Excavation would begin from the water's edge and work towards Crisp Road (on HPS Phase II), and would keep the material handling on the non-screened area to minimize any cross contamination. Material would first be excavated to depth and stockpiled near the sorting equipment for access with a loader. Material would next pass through a screen to remove oversized material and cobbles, then through a tumbler to break up clods of dirt. It would then fall onto a conveyor system and pass through a bank of detectors to measure the level of radiological activity, if any. Material that fails the desired screening level would be directed to a separate conveyor and the remaining material would be directed to a different conveyor and stockpiled for reuse as backfill. Any material that exceeds screening levels or re-use criteria would be stockpiled and sampled for off-site disposal at an approved facility. As the excavation proceeds, the screening plant and conveyor system would be moved, staying on non-cleared areas to prevent cross-contamination. Once the excavation has met the required depth (excavation would extend no deeper than the water table), verification sampling would be performed to ensure radiological constituents have been removed. Once verified clean, a 12-inch-wide concrete retaining wall would be installed from the bottom of the excavation to two feet above

final grade to act as a permanent vertical barrier between the radiologically impacted area and the newly cleared area for street construction. Material verified as clean would be used as backfill to bring the site back up to grade for street construction.

In addition to the specific safety protocols and control measures described above, the approved removal action workplans would incorporate applicable requirements to control potential impacts from dust and other air emissions and to prevent migration of contaminants to groundwater or stormwater, as set forth in Table III.K-2. To reduce the impact related to exposure to contaminated soil during construction of the Yosemite Slough bridge, the following mitigation measure shall be implemented.

MM HZ-9 *Navy-approved workplans for construction and remediation activities on Navy-owned property. (Applies only to the portions of HPS Phase II on Navy-owned property). Construction activities and remediation activities conducted on behalf of the Agency or the Project Applicant, on Navy-owned property shall be conducted in compliance with all required notices, restrictions, or other requirements set forth in the applicable lease, easement, or license or other form of right of entry and in accordance with a Navy-approved workplan. This mitigation measure also requires that such activities be conducted in accordance with applicable health and safety plans, dust control plans, stormwater pollution prevention plans, community involvement plans, or any other documents or plans required under applicable law. The City/Agency will access Navy property through a lease, license, or easement. The City/Agency shall not undertake any activity or approve any Project Applicant activity on Navy-owned property until the Navy and other agencies with approval authority have approved a workplan for the activity. The requirement to comply with the approved work plans shall be incorporated into and made a condition of any City/Agency approvals related to activities on Navy property. This measure shall be implemented for HPS Phase II through a process established by the City or Agency as explained in MM HZ-1b.*

The general requirement of mitigation measure MM HZ-9 would apply to the Yosemite Slough bridge remediation activities by requiring that remediation activities conducted in conjunction with the construction of the Yosemite Slough bridge be performed only after approval by the FFA Signatories and the CDPH, of a removal action workplan for excavation of radiologically contaminated materials. The safety protocols and control measures expected to be included in that workplan. This mitigation measure further requires the excavation to be conducted in accordance with the requirements of that workplan and of other applicable health and safety plans, dust control plans, stormwater pollution prevention plans or any other document or plan required under applicable law, including, but not limited to applicable requirements illustrated in Table III.K-2.

As a result of these Project controls and mitigation measures, the potential for exposure to hazardous materials during remediation activities conducted in conjunction with the construction of the Yosemite Slough bridge would be reduced to less-than-significant levels.

Impact HZ-10: Exposure to Hazardous Materials during Construction of Shoreline Improvements

Impact of Candlestick Point

Impact HZ-10a **Construction in the shoreline areas at Candlestick Point would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of sediment or soil that may contain chemical contaminants. (Less than Significant with Mitigation)** ***[Criteria K.b and K.d]***

The Project would include shoreline improvements along Candlestick Point. These improvements would include the placement of additional (rock) riprap, creation of a sandy recreational beach at the mid-point of the Wind Meadow reach along the Eastern Shoreline, and creation of new tidal habitat in several locations.

As described in the Setting and in Impact HZ-1a, there are no known releases of hazardous materials requiring remediation in the portions of Candlestick Point bayward of the 1851 high-tide line, but the detection of low-levels of hazardous materials in 1998 and general knowledge of the types of material that can be in Bay fill lead to the conclusion that there is a potential for exposure to hazardous materials from development activity in these areas. Installation of the proposed shoreline improvements have the potential to disturb sediments overlying and/or derived from Bay fill, which could contain hazardous materials. The primary effect of disturbance of sediment that could contain hazardous materials would be re-suspension of hazardous materials adhering to sediment, which could enter surface water, which could, in turn, affect water quality and/or aquatic species.

Impact HY-1a in Section III.M provides a comprehensive description of the required permits and additional mitigation that would require site-specific controls to minimize sediment disturbance to reduce water quality effects. Mitigation measures MM HY-1a.1 and MM HY-1a.2 require that the Stormwater Pollution Prevention Plan (SWPPP) include specific best management practices (BMPs) to minimize the potential transport of sediment, debris, and construction materials to the Lower Bay during construction of shoreline improvements. Where possible and necessary, excavation and construction of improvements would be implemented prior to removal of existing structures. Materials management and construction BMPs would be implemented to minimize potential discharges to the Lower Bay or disturbance of sediment. All BMPs would be included in related permits/permit requirements obtained for construction of Shoreline Improvements (e.g., USACE 404 permit, SFRWQCB 404 certification, BCDC/DMMO permit). Following removal/replacement of structures, exposed surfaces would be stabilized with hardscape, vegetation, or bioengineered features, as feasible.

Impact BI-2, Impact BI-4a, Impact BI-10a, Impact BI-11a, and Impact BI-12a in Section III.N (Biological Resources) describe the effect of shoreline sediment disturbance on aquatic species and mitigation measures to reduce those effects. The general requirements of mitigation measures MM BI-4a.1 and MM BI-4a.2 (described in Section III.N) would reduce the effects of construction-related activities on aquatic habitat by requiring that appropriate permits be obtained from the USACE, SFRWQCB, BCDC, and other agencies as applicable (MM BI-4a.1) and implementing construction BMPs (MM BI-4a.2) to reduce and/or prevent impacts to waters of the United States, including aquatic habitats.

The potential risks to construction workers and the public would be reduced through implementation of mitigation measure MM HZ-1a, which would reduce effects related to exposure of known contaminants at Candlestick Point, including construction activities at CPSRA, by requiring compliance with Article 22A or an equivalent process to identify and manage potential hazards. In the event previously unidentified contamination is found in sediments during shoreline improvements, implementation of mitigation measure MM HZ-2a.1 would ensure the appropriate steps are taken to minimize exposure to people and the environment.

Therefore, there would not be a significant hazard to the public or the environment from hazardous materials as a result of shoreline improvements in Candlestick Point. Implementation of mitigation measures MM BI-4.a.1, MM BI-4.a.2, MM HY-1a.1, MM HY-1a.2, MM HZ-1a, and MM HZ-2a.1 would ensure that potential adverse effects on human health and the environment would be reduced to a less-than-significant level.

Impact of Hunters Point Shipyard Phase II

Impact HZ-10b **Construction in the shoreline areas at HPS Phase II would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of sediment or soil that is radiologically affected or that may contain chemical contaminants. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

The Project would include several shoreline improvements, which are described in Chapter II. Many of the improvements would involve work within the Bay (e.g., the marina, modifications to berths, wharves, and drydocks, installation of marina breakwater). For such features, and others, that would occur within the Bay and do not require anchoring, foundations, or other contact with sediment, submerged lands, or rock, the primary environmental effects associated with those improvements would be related to water quality or increased turbidity, which could affect aquatic species. Refer to Impact BI-2, Impact BI-4b, Impact BI-5b, Impact BI-10b, Impact BI-11b, and Impact BI-12b in Section III.N for additional information about those effects. Some of the proposed shoreline improvement activities that may potentially disturb sediments and impact submerged lands include pile-driving, construction of rock buttresses, dredging, riprap installation, marina construction and installation of natural-looking shoreline protection using fill and articulated concrete block (ACB) mats.

HPS Phase II parcels where shoreline improvements affecting sediment could occur are limited to Parcels B, C, E/E-2, and F. All sediments that may be affected by these shoreline improvements, however, are contained within Parcel F. Because of the known presence of contamination in sediment within Parcel F, the Navy is in the process of preparing a ROD for Parcel F. Once a ROD is approved, remediation can occur. Any remedies for radiologically impacted material will be implemented by the Navy prior to transfer. The options for remediating potentially affected sediment could include removing the sediment or capping in place as per the ROD. Sediments found to be non-hazardous would not require remediation and will be left in place. It is also possible that shoreline improvements could occur after the Navy has capped sediments in place and these improvements could disturb the cap. Shoreline improvements would be completed in accordance with mitigation measures MM HZ-1b, MM HZ-10b, MM HZ-12, and the RMPs.

As previously described, RODs have been finalized for Parcels B, D-1, G, UC-1 and UC-2. RODs have not been completed for Parcels C, D-2, E/E-2, and F but are expected in the late 2009 to summer 2012

timeframe. Depending on the development schedule relative to the remaining RODs and their subsequent implementation, sediments could be remediated by the Navy under CERCLA in advance of Project Applicant activities, in which case all necessary administrative and physical controls would be in place that would minimize potential hazards to the occupants, the public, construction workers and the environment from exposure to hazardous materials in sediment. If the shoreline improvements require disturbance of sediments capped in place, work will be completed in accordance with mitigation measures MM HZ-1b, MM HZ-10b, and MM HZ-12.

This impact analysis assumes a shoreline improvement scenario in which the Navy does not implement the selected remedy in the ROD for these parcels (with the exception of radiological contamination), and the Agency or the Project Applicant implements the remaining remediation activities in conjunction with shoreline improvement activities with appropriate regulatory oversight. Such remediation and shoreline improvement activities are considered part of the Project, and their potential impacts are analyzed here.

Because contaminants have been identified in those parcels for which a remedy has been selected but not yet implemented, construction of the shoreline improvements has the potential to disturb sediment or soil that may contain chemical contaminants at levels that could expose construction workers, the public, or the environment to hazardous materials if not properly managed.

(At some Navy shipyards, ordnance and munitions have been discovered in offshore sediments as a result of offloading from ships during wartime. There is no evidence of this at HPS. HPS is not considered a Military Munitions Program Site, so hazards associated with munitions are not anticipated.)

One type of improvement is a development-related remediation activity that is expected to be the responsibility of the Agency or Project Applicant under the Parcel B ROD. That activity involves construction of a shoreline revetment to prevent erosion of soil contaminants into the Bay. The Parcel B ROD requires construction and/or reconstruction of a revetment at two portions of the Parcel B shoreline: a 1,200-foot segment near IR Site 26, and a 230-foot segment near IR Site 23. The revetment would consist of 500-pound stones underlain by geotextile material. It is expected that a temporary cofferdam, water-filled barrier tube, select sheet piles or equivalent would be used during construction of the revetment.

Other shoreline improvements that could disturb sediment include: marina construction, a rock buttress along the submarine docks and repairs to or replacement of the caisson piles at the wharf along berths 55 to 61 (Parcel B); rock or sand buttress along Drydock 2, 3 and 4 only if sediment is in the drydock prior to buttress construction (Parcel C); and natural edge/riprap-protected slope for the proposed grasslands ecology park (Parcel E/E-2).

The following outlines the process that would be followed by Agency or Project Applicant in conjunction with development activities with appropriate regulatory oversight to manage potentially contaminated sediments that could be affected by Project shoreline improvements.

For sediments identified for removal, remedial design documents will be prepared and submitted to USEPA, DTSC, RWQCB, and, if necessary, the Navy and CDPH for approval. A Dredged Material Management Office (DMMO) permit will be required (refer to Section III.K.3). The design documents would incorporate the necessary shoreline improvements required for each specific area (e.g., rock buttressing, pile replacement, backfilling, riprap, or installation of natural-looking shoreline protection

using fill and ACB mats) such that remediation (removal of sediment and any necessary dredging) and shoreline improvements are performed under the same regulatory approvals and permits.

In instances where sediments are determined to be non-hazardous and allowed to be left in place but the proposed shoreline improvements require sediment removal, a dredging plan would be prepared and submitted to USEPA, DTSC, RWQCB, and, if necessary, the Navy and CDPH for approval. A DMMO permit would be required. Following sediment removal, improvements would proceed as described in the Project Description.

More specific approaches are proposed for locations where the shoreline improvements are proposed and the selected ROD remedy is to leave sediments in place with covers or caps, as described below. These additional measures are needed to ensure that already-completed remedies (e.g., the cover at E/E-2) are not compromised.

a. The installation of the rock buttress at Drydocks 5–7 (Parcel B) would be evaluated to determine if the placement of the rock would compromise the integrity of the Navy-installed cover. If the cover could be compromised, appropriate design documents describing how construction activities would be performed to mitigate environmental risk and to restore the cap would be prepared and submitted to the USEPA, DTSC, RWQCB, and, if necessary, the Navy and CDPH for approval. Review by the DMMO may also be obtained.

b. If the inspection of the steel piles below the wharf at berths 55–61 (Parcel B) shows that piles need to be replaced by driving new piles, then proper design documents describing (1) how construction activities would be performed to mitigate environmental risk and (2) restore the cap would be prepared and submitted to USEPA, DTSC, RWQCB, and, if necessary, the Navy and CDPH for approval. Review by the DMMO may also be obtained.

c. Two options are possible for Drydocks 2, 3, and 4 (Parcel C). If the cap remains in place, appropriate design documents describing how construction activities (rock buttressing) would be performed to mitigate environmental risk and restore the cap would be prepared and submitted to USEPA, DTSC, RWQCB, and, if necessary, the Navy and CDPH for approval. If the sediment and cap would need to be removed, appropriate design documents would be produced for regulatory approval (USEPA, DTSC, RWQCB, and, if necessary, the Navy and CDPH) describing the construction activities required for removal of the existing cap and contaminated sediment below. A plan describing removal of contaminated sediment and the methods used to determine that all contamination has been removed would be prepared and submitted to these agencies for approval. Following regulatory approval and the removal of the sediment from the drydocks, installation of the rock buttress may be completed as originally planned. Review by the DMMO may also be obtained.

d. The installation of natural-looking shoreline protection using fill and Articulated Concrete Block (ACB) mats along the shoreline of Parcels E and E-2 would be evaluated to determine if the placement of fill cover and ACB mats would compromise the integrity of the Navy-installed cover and riprap. If the cover may be compromised, design documents describing how construction activities would mitigate environmental risk and restore the cap would be prepared and submitted to USEPA, DTSC, RWQCB, and, if necessary, the Navy and CDPH for approval. Even if it is determined that the cover would not be impacted by Project activities, review by the DMMO would likely be required.

MM HZ-10b *<u>Regulatory Agency–Approved Workplans and Permits for Shoreline Improvements.</u> Prior to undertaking any shoreline improvement activities that would affect sediment at HPS Phase II, the Agency or its contractor or Project Applicant shall prepare appropriate design documents and submit to USEPA,*

DTSC, RWQCB, and, if necessary, the Navy and CDPH for approval. A Dredged Material Management Office (DMMO) permit shall be obtained. The design documents shall incorporate the necessary shoreline improvements required for each specific area (e.g., including, but not limited to, rock buttressing, pile replacement, backfilling, riprap, or installation of natural-looking shoreline protection using fill and ACB mats) such that remediation (removal of sediment and any necessary dredging) and structural improvements are performed under the same regulatory approvals and permits.

Prior to undertaking any shoreline improvement activities that could affect contaminated sediments left in place and covered or capped with a Navy-installed remedial measure, or that would involve pile replacement in such areas, the Agency or its contractor or Project Applicant shall prepare appropriate design documents that: (1) describes how the cover or cap would be inspected to determine whether proposed shoreline improvements would adversely affect the cover or cap; and (2) describes how construction activities would be performed to mitigate environmental risk and to restore the cover or cap. The design documents shall be submitted to USEPA, DTSC, RWQCB, and, if necessary, the Navy and CDPH for approval. A DMMO permit shall be obtained, as applicable.

Prior to undertaking any shoreline improvements that could encounter contaminated sediments, the Agency or its contractor or Project Applicant shall comply with all requirements incorporated into the design documents, work plans, health and safety plans, dust control plans, and any other document or plan required under the Administrative Order of Consent. This includes all restrictions imposed pursuant to a CERCLA ROD, Petroleum Corrective Action Plan, FOSET, including restrictions imposed in deeds, covenants, and requirements set forth in Land Use Control Remedial Design Documents, Risk Management Plans and health and safety plans. Prior to obtaining a grading, excavation, site, building, or other permit from the City that authorizes remedial activities, SFDPH shall confirm that the work proposed complies with the applicable plans required by the Administrative Order of Consent. This measure shall be implemented through additions to Article 31 or through an equivalent process established by the City or Agency as explained in MM HZ-1b.

This mitigation measure requires that all shoreline activities that could affect sediment be conducted in accordance with agency-approved design documents, applicable health and safety plans, DCPs, or any other documents or plans required under applicable law or laws, including but not limited to applicable requirements shown in Table III.K-2. As a result of these Project controls and mitigation measures, the potential for exposure to hazardous materials during shoreline improvements construction activities would be reduced to less-than-significant levels.

Mitigation measures identified in Section III.M and Section III.N further reduce this impact. Mitigation measures MM HY-1a.1 and MM HY-1a.2 require that the Stormwater Pollution Prevention Plan (SWPPP) include specific best management practices (BMPs) to minimize the potential transport of sediment, debris, and construction materials to the Lower Bay during construction of shoreline improvements. The general requirements of mitigation measures MM BI-4a.1 and MM BI-4a.2 (described in Section III.N) would reduce the effects of construction-related activities on aquatic habitat, including special-status fish, by requiring that appropriate permits be obtained from the USACE, SFRWQCB, BCDC, and other agencies as applicable (MM BI-4a.1) and implementing construction BMPs (MM BI-4a.2) to reduce and/or prevent impacts to waters of the United States, including aquatic habitats. Potential impacts on eelgrass beds would be mitigated through mitigation measure MM BI-5b.4, which also requires BMPs specific to that sensitive natural community. Mitigation measure MM BI-12b.1 identifies additional sediment management controls to reduce the effects of construction-related activities on aquatic species.

With implementation of mitigation measures MM BI-4a.1, MM BI-4a.2, MM BI-5b.4, MM BI-12b.1, MM HY-1a.1, MM HY-1a.2, and MM HZ-10b, along with applicable regulations and permits, potential impacts related to exposure to hazardous materials releases from contaminated sediments that could be disturbed during proposed shoreline improvements in HPS Phase II would be reduced to a less-than significant level.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-10 **Construction activities associated with the Project in shoreline areas would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of sediment or soil that may contain chemical or radiological contaminants. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

The proposed shoreline improvements along Candlestick Point and Hunters Point Phase II have the potential to disturb sediments that could contain hazardous materials. If sediment containing hazardous materials were released to the water, this could adversely affect water quality, and could also impact aquatic species. With implementation of mitigation measures MM BI-4a.1, MM BI-4a.2, MM BI-5b.4, MM BI-12b.1, MM HY-1a.1, MM HY-1a.2, MM HZ-1a, MM HZ-2a.1, MM HZ-10b, along with applicable regulations and permits, potential impacts related to exposure to hazardous materials releases from contaminated sediments that could be disturbed during proposed shoreline improvements would be reduced to a less-than significant level by ensuring locations where sediments containing hazardous materials have been identified, plans are developed and implemented to manage the sediment, all appropriate permits have been obtained, and best management practices (BMPs) are implemented.

Impact HZ-11: Exposure to Hazardous Materials While Constructing Infrastructure on Navy-Owned Property

Impact HZ-11 **Construction activities associated with the Project on Navy-owned property, including improvements to existing utilities and installation of new underground utilities, would not expose occupants, construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of soil, sediment, or groundwater that may contain contaminants from historic uses, including radiological contaminants. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

It is expected that development of properties the Navy has transferred would require underground utilities be installed across land the Navy still owns and that may still be undergoing remediation. As described above, utility trenches have the potential to create a horizontal conduit for chemical contaminants contained in soil vapors or shallow groundwater to migrate along the permeable soils that would be placed as trench backfill. The easement or other legal instrument providing a right to access the Navy property would require underground utility excavation activities to be conducted in accordance with a Navy-approved workplan that will require implementation of measures to prevent such migration.

Mitigation measure MM HZ-1b would apply to development activities that take place before remediation is complete (e.g., if property is subject to an early transfer) or accessed through a license or easement.

MM HZ-1b requires the Project Applicant submit documentation to the SFDPH that the work will be undertaken in compliance with all restrictions imposed pursuant to the ICs and transfer documents.

The general requirement of mitigation measure MM HZ-9 would also apply to underground utility construction activities by requiring that such activities be conducted only after approval of a workplan by the Navy, and if required, by the other FFA Signatories. This mitigation measure would also require such underground utility construction activities be conducted in accordance with applicable health and safety plans, DCPs, or any other documents or plans required under applicable law or laws. As a result of these Project controls and mitigation measures, the potential for exposure to hazardous materials during underground utility construction at HPS Phase II would be reduced to less-than-significant levels.

Impact HZ-12: Remediation Activities Conducted in Conjunction with Development Activities at HPS Phase II Early Transfer Parcels

Impact HZ-12 **Remediation activities conducted on behalf of the City or Project Applicant at the HPS Phase II parcels transferred prior to completion of remediation in an "early transfer" would not expose remediation and construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of soil, sediment, and/or groundwater that may contain contaminants from historic uses. (Less than Significant with Mitigation)** ***[Criteria K.b and K.d]***

Although the ongoing remediation activities conducted by the Navy under the FFA are not part of the Project, if any of the parcels are transferred prior to completion of remediation in an "early transfer" as described in the Regulatory Framework, the Agency or the Project Applicant may instead implement the remaining remediation activities in conjunction with development activities with appropriate regulatory oversight. Such remediation activities conducted by or on behalf of the Agency or Project Applicant are considered part of the Project, and their potential impacts are analyzed here.

The Navy and the Agency are currently evaluating an early transfer for Parcel B (except IR7/18) and Parcel G. Parcel C, and portions of Parcels D and E also are being considered for potential early transfers after the transfer of Parcels B and G. Early transfers are not being considered for Parcel E-2, the Parcel E shoreline area, or Parcel F. At parcels subject to early transfer, the Navy would be responsible for securing an approved ROD selecting the remedies prior to property transfer. The Navy would be responsible for completing all remediation activities associated with radiological materials prior to property transfer. Because the Navy has already conducted significant remedial activities, it is expected that the Navy may complete, before transfer, the initial installation of groundwater treatment systems and soil vapor extraction systems and conduct major soil excavations.

The remedial activities for which the Agency or the Project Applicant may be responsible include: covering Bay Fill areas with clean soil or other impervious surfaces such as pavement, concrete, or buildings; operating groundwater treatment systems and soil vapor extraction systems; implementing parcel-wide groundwater monitoring programs; performing soil vapor investigations to determine where it may be necessary to install soil vapor barriers underneath new buildings, and installing such barriers; reconstructing the shoreline revetment wall to protect ecological receptors along the Bay shoreline; excavating small "hot spots" in soil; and implementing and enforcing institutional controls.

Under the legal agreements that would be executed as part of an early transfer, the Agency and the Project Applicant are also likely to assume responsibility for remediating previously unidentified hazardous material releases discovered during redevelopment, to the extent the costs of such remediation are paid by environmental insurance secured with funds provided by the Navy. Those legal agreements are also expected to specify that the Navy will retain responsibility for addressing any radiological material releases and for addressing unidentified hazardous materials releases at HPS to the extent the costs of addressing such releases are not paid by environmental insurance secured with funds provided by the Navy. These legal agreements among the Navy, Agency, the Project Applicant, and the insurer would not alter the obligations to implement the mitigation measures identified in this EIR.

The remedial activities for which the Agency or the Project Applicant would be responsible at early-transferred parcels would be conducted by experienced engineering firms and environmental remediation contractors, as is also the case with the ongoing work supervised by the Navy. Under the AOC, which would be signed by the Agency, the Project Applicant, USEPA, DTSC, and the RWQCB before any early transfer, the Agency and Project Applicant's remedial activities would be subject to all of the same requirements, and subject to all of the same review by the FFA Signatory environmental agencies, as the Navy's ongoing work.

The remedial design documents and workplans that would be reviewed by the environmental agencies pursuant to the AOC include health and safety plans and would incorporate numerous requirements to ensure that the remedial activities would not cause exposures to hazardous materials that could pose a significant risk to human health and the environment. Table III.K-2 shows the potential environmental effects of different remedial activities and the measures that would be required in the documents and workplans approved by the environmental agency to control those effects.[335]

Many of the potential impacts of construction activities discussed in this section are also potential impacts of remediation activities. Therefore, the text notes where the discussion of impacts and mitigation measures referenced in those subsections would apply to site investigation and remediation activities.

Although the AOC will require the types of control measures described above and in Table III.K-2 independent of this EIR, to ensure compliance with these controls, mitigation measure MM HZ-12 would require SFDPH to ensure that before development occurs, the Agency or the Project Applicant and their contractors have incorporated all applicable requirements into remedial design documents, work plans, health and safety plans, DCPs and any other document or plan required under the AOC or other applicable law, as a condition of development, as illustrated by the requirements set forth in Table III.K-2, and to conduct work in accordance with the RMPs. As a result of those Project controls and mitigation measures, the potential impact of exposure to hazardous materials during remediation activities conducted on behalf of the Agency or the Project Applicant in conjunction with development of HPS Phase II would be reduced to less-than-significant levels.

[335] This table includes remedial activities which will not be the responsibility of the Agency or the Project Applicant and activities on parcels which will not be early-transferred. These activities are included because they are relevant to the discussion earlier in this section of the impacts of occupancy of portions of HPS in proximity to other portions where Navy remediation may still be ongoing.

MM HZ-12 *Compliance with Administrative Order on Consent at Early Transferred Parcels. (Applies only at HPS Phase II.) Prior to undertaking any remediation activities at HPS Phase II on property that the Navy has transferred to the Agency as part of an early-transfer, the Agency or its contractor or Project Applicant shall comply with all requirements incorporated into remedial design documents, work plans, health and safety plans, dust control plans, community involvement plans, and any other document or plan required under the Administrative Order on Consent. This includes all notices, restrictions, and requirements imposed pursuant to a CERCLA ROD, Petroleum Corrective Action Plan, FOSET, including restrictions imposed in deeds, covenants, and requirements set forth in Land Use Control Remedial Design Documents, Risk Management Plans, community involvement plans, and health and safety plans. Prior to obtaining a grading, excavation, site, building, or other permit from the City that authorizes remedial activities, SFDPH shall confirm that the work proposed complies with the applicable plans required by the Administrative Order of Consent. This measure shall be implemented through a requirement in the potential additions to Article 31 imposing requirements to parcels other than Parcel A or through an equivalent process established by the City or Agency.*

The specific types of requirements anticipated to be included in these documents and plans are illustrated in Table III.K-2. With the implementation of these mitigation measures, potential impacts from remediation activities conducted in conjunction with development activities at HPS Phase II early transfer parcels would be reduced to a less-than significant level.

Impact HZ-13: Exposure to Hazardous Materials Contamination During Construction of Off-Site Roadway Improvements

Impact HZ-13 **Construction of off-site roadway improvements would not expose construction workers, the public, or the environment to unacceptable levels of hazardous materials as a result of the disturbance of soil or groundwater that may contain contaminants. (Less than Significant) *[Criterion K.b]***

Location of Off-Site Roadway Improvements

The Project would improve existing roadways to serve Candlestick Point and HPS Phase II and surrounding Bayview and Hunters Point neighborhoods as described in Chapter II. Those improvements include:

- **Roadway Improvements:** Ingalls Street (from Carroll Avenue to Thomas Avenue), Thomas Avenue (from Ingalls Street to Griffith Street), and Griffith Street (from Thomas Avenue to Crisp Road) would be converted from two-lane to four-lane facilities. Existing on-street parking would be removed on Ingalls Street and Griffith Street to create the new facilities. Parking would be retained on both sides of Thomas Avenue. A new signal would be installed at the Thomas Avenue/Ingalls Street intersection.
- **Streetscape Improvements:** Innes Avenue/Hunters Point Boulevard, Palou Avenue, and Gilman Avenue would serve as primary access corridors from the north for pedestrians, bicyclists, transit vehicles, and automobiles. Streetscape improvements would include street trees, sidewalk plantings, furnishings, and paving treatments along Innes Avenue/Hunters Point Boulevard, Palou Avenue (from Crisp Road to Third Street), and Gilman Avenue.
- **Harney Way Improvements:** The existing four-lane roadway would be rebuilt as a new four-lane facility with right-of-way reserved for an additional westbound lane to be built in the future as needed for increased traffic levels. Six lanes would be constructed west of Thomas Mellon Drive to connect with the future modifications to the US-101 interchange. Two exclusive Bus Rapid Transit (BRT)

lanes would be constructed adjacent to the roadway in addition to the auto lanes. Left-turn lanes on eastbound Harney Way would be installed at the Thomas Mellon Drive and Executive Park Boulevard intersections to provide access to Executive Park.

- **Palou Avenue Transit Preferential Street:** One Muni line would be extended along Palou Avenue to serve the Hunters Point Shipyard Transit Center. In addition, two other lines would operate along Palou Avenue with service near the Project. In order to provide efficient, attractive service on these lines, transit preferential treatments including transit-priority technology would be implemented, including installation of new traffic signals along Palou Avenue to Third Street. To improve pedestrian comfort and the accessibility of transit in this corridor, new bus shelters would be installed and the street would be upgraded with ADA ramps, bulbouts, and crosswalks.

The Site History/Initial Site Assessment technical report prepared for the Bayview Transportation Improvements Project (currently under environemental review) reviewed environmental conditions at most of the locations described above where the off-site improvements may involve disturbance of soil or the existing asphalt cover.[336] At Griffith Street, Ingalls Street, and Carroll Avenue, the report concluded that historic and current land uses indicate the potential for hazardous substances to have been released at some locations along those roadways such that soil could have been affected. The Site History/Initial Site Assessment technical report did not include the segment of Palou Avenue where improvements are proposed. Previous investigations that identified historic uses, USTs, and sampling results along the alignments, along with a review of agency databases, show that many of the sites identified in the above-referenced Site History/Initial Site Assessment report have received regulatory closure. However, some locations may still require investigation or remediation, and there may be new sites that have not been comprehensively evaluated for the presence of hazardous materials contamination in soil at the specific locations where soil disturbance could occur.

Description of Construction Activities at Off-Site Roadway Improvements

Construction activities for off-site street improvements include the following: demolition of existing street and sidewalk; protection, replacement or relocation of existing underground utilities; signage and traffic light installation; asphalt/concrete paving; curb, gutter and ramp installation; striping; bus shelter installation; landscape installation including trees, shrubs and irrigation systems; street lighting installation; and electrical connection installation.

Typical excavation depths associated with these types of activities would range from 1 to 3 feet for roadway (including sidewalk, curb, gutter). For utility improvements along roadways, trench depths could be as shallow as 4-5 feet (e.g., landscape irrigation lines, dry utilities) to as much as 20-30 feet for storm drain and sewer facilities, depending on size and type. The width of disturbed area for roadways would depend on the right-of-way, but generally would range from 60 to 100 feet. For utility improvements, trenches would be approximately 1 to 4 feet wide for dry utilities and water lines, but could be up to 20 to 30 feet wide for storm and sewer components.

Off-site street improvements would be performed by first removing the existing pavement section. The existing pavement section consists of asphalt, concrete and an aggregate or Portland concrete cement (PCC)

[336] BASELINE Environmental, Bayview Transportation Improvements Project, Technical Report, Site History/Initial Site Assessment, June 2009.

base material. The existing pavement section would be removed by scraping the paving section away from the sub-base utilizing typical street construction equipment. The demolished material would either be reused as backfill or disposed of by trucking it to an off-site landfill that accepts construction debris, including asphalt, in accordance with pre-determined City haul route(s). Existing utilities would be protected in place, replaced, or relocated as needed prior to construction of the new street. The new asphalt/concrete pavement section would be installed per City structural section requirements and include an eight-inch PCC base. The curb, gutter, and ramps would be constructed of PCC. After installation of the new street structural sections the new street surface would be painted per a striping plan approved by the City. Other street improvements may then include signage, traffic lights, bus shelters, and street light installation.

The width and depth of proposed off-site improvements would determine the extent to which contaminants (if any) could be encountered during the construction activities.

The majority of the off-site roadway improvements are bayward of mean high tide line and thus subject to the requirements of *San Francisco Health Code* Article 22A, including, if required, the preparation and implementation of a site mitigation plan. Compliance with Article 22A would ensure that impacts from exposure to hazardous materials associated with off-site roadway improvements would be less than significant. No mitigation is required.

Impact HZ-14: Exposure of Ecological Receptors to Hazardous Materials

Impact of Candlestick Point

Impact HZ-14a **Construction at Candlestick Point would not expose ecological receptors to unacceptable levels of hazardous materials as a result of the disturbance of soil, sediment, and/or groundwater that may contain contaminants from historic uses. (Less than Significant with Mitigation) *[Criterion K.b]***

Site preparation would include deep excavations for large structures such as residential towers; installation of foundation piles; trenching for utility lines; grading and compaction; and other earth-disturbing activities. Additionally, there would be roadway improvements. These construction activities would involve grading, trenching, compacting, and excavating, which would result in soil and/or fill being handled, stockpiled, and moved on site.

Section III.N identifies the fish and wildlife species that could be affected by Project construction. These species include a broad range of resident and migratory fish and wildlife species. Common wildlife includes a number of species of invertebrates, reptiles and amphibians, birds, and mammals (terrestrial and aquatic). Common aquatic resources include many species of fish, shellfish, and mollusks.

There are no sites with known contamination requiring remediation at Candlestick Point, and no immediate risks to fish or wildlife have been identified for the Candlestick Point portion of the Project. However, as described in Impact HZ-2a, there is a potential for hazardous materials to be present in fill or soil materials bayward of the 1851 high tide line, or there is a possibility that previously unknown contamination could be discovered during site development. The reader is also referred to Impact HZ-1a and Impact HZ-2a for descriptions of the processes for determining whether contaminants are present in fill or soil, and, if contaminants are identified, mitigation measures MM HZ-1a and MM HZ-2a.1 prescribe the types of actions required by a site mitigation plan and unknown contaminant contingency plan.

To the extent that the property under development in areas underlain by fill or soils that could contain hazardous waste, soil disturbance and associated stockpiling and on-site soil movement could provide potential pathways through which fish and wildlife species could be exposed to contaminants in soil or fill material. Soil disturbance could be the result of general construction activities in which previously unidentified contaminants have been discovered, or it could be the result of implementation of mitigation deemed necessary through Article 22A testing to reduce an environmental hazard. The site mitigation report required under Article 22A would determine if there is a significant environmental risk, which would include risks to ecological systems, and if so, recommend measures that will mitigate the risks.

The primary environmental mechanisms for ecological exposure during soil disturbance would be (1) direct species contact with the fill or soil containing contaminants (e.g., birds landing on or rodents burrowing into stockpiled materials); (2) stormwater runoff from exposed soils or fill, or soils spilled onto roads during transport, which could carry contaminants into aquatic environments, where fish and benthic invertebrate species could be affected; or (3) windblown dust, which could be inhaled by terrestrial and avian species, or that could be deposited on surface water, where aquatic organisms could be affected.

There are controls and mitigation measures identified in this EIR that would reduce potential impacts on human populations, which would also help reduce the impact on ecological systems, as explained below. In addition, there are environmental conditions that would also reduce the potential for adverse impacts.

For example, the site mitigation plan required under Article 22A would incorporate measures, such as covering stockpiles, which would minimize the potential for avian and terrestrial species to have direct contact with soil. Implementation of measures to control stormwater runoff during construction would control the discharge of potential chemicals adhered to soil in the runoff. Mitigation measures MM HY-1a.1 and MM HY-1a.2 would require preparation of a SWPPP would be required to identify the specific measures and BMPs applicable to Candlestick Point construction activities in the event of a spill of construction materials or exposure of hazardous materials. This would reduce the likelihood of contaminants being conveyed to near-shore and offshore environments, which would reduce the risk to the aquatic environment and species that rely on that habitat (e.g., birds and mammals).

As described, dust control measures are required both by local ordinance and by BAAQMD. Implementation of dust control measures (mitigation measure MM HZ-15) would effectively reduce the potential for windborne dust that could affect fish and wildlife species. However, natural environmental conditions would also be a factor in minimizing the potential for contaminated dusts to adversely affect ecological systems. Avian species could be exposed to windblown dust through inhalation and ingestion during preening and prey consumption. Although various avian species use Candlestick Point for nesting and foraging, the mobility of the bird species results in their use of a relatively large home range and foraging range. Due to this mobility, avian species would not be present in one foraging area for an extended period of time in which they could receive substantial exposure to contaminants in dust. Windblown dust deposited onto water bodies could result in direct exposure to filter-feeding mollusks and other aquatic species. Additionally, excessive deposition of dust onto surface water, such as the Bay, could increase turbidity, which could, in turn, decrease light penetration into water and available oxygen. Even if dust control measures were not implemented, dusts generated by wind during construction would be dispersed over a relatively large area, with no single area receiving a sufficient volume of dust to generate a significant exposure to species.

Ponded water in open excavations and trenches (if contaminants were present and if standing water remained) could also present an ecological risk. However, because dewatering would be necessary to ensure proper construction conditions, groundwater would be removed routinely and frequently. Groundwater would either be pumped into the sewage system or to the Bay in accordance with the Industrial Waste Ordinance of the *Public Works Code*. The sewage system is a closed system, so there would be no direct exposure pathway to fish or wildlife. If shallow groundwater were to be pumped directly into the Bay as a necessary by-product of construction dewatering, the discharger would be required to notify and obtain approval of the RWQCB, as described in Section III.M (mitigation measure MM HY-1a.3). Any groundwater proposed for discharge from the Project site into the Bay must meet strict water quality standards established by the San Francisco Bay Basin Plan as defined by the RWQCB, and may have to be treated before discharge into the Bay to avoid potential degradation of the Bay's water quality. Furthermore, dischargers are required to meet stringent monitoring standards established by the RWQCB (and to a certain extent, the SWRCB) to ensure compliance under this permitting system. This would ensure potential aquatic impacts are minimized.

As explained in Impact HZ-10a, mitigation measures identified in Section III.N (Biological Resources) would also reduce impacts on ecological receptors. The general requirements of mitigation measures MM BI-4a.1 and MM BI-4a.2 (which are fully described in Section III.N) would reduce the effects of construction-related activities on aquatic habitat by requiring that appropriate permits be obtained from the USACE, SFRWQCB, BCDC, and other agencies, as applicable (refer to MM BI-4a.1) and implementing construction BMPs to reduce and/or prevent impacts to waters of the United States, including aquatic habitats (refer to MM BI-4a.2).

Compliance with the procedures described above would ensure that soil handling, stockpiling, and movement, and construction dewatering within Candlestick Point would not present a significant risk to the ecological environment. Therefore, with implementation of Article 22A, and mitigation measures MM HZ-1a, MM HZ-2a.1, MM HZ-15, MM HY-1a.1, MM HY-1a.2, MM HY-1a.3, MM BI-4a.1, and MM BI-4a.2, potential construction ecosystem impacts related to handling, stockpiling, and transport of contaminated soil (including shoreline sediments) and groundwater would be reduced to less-than-significant levels.

Impact of Hunters Point Shipyard Phase II

Impact HZ-14b **Construction at HPS Phase II would not expose ecological receptors to unacceptable levels of hazardous materials as a result of the disturbance of soil, sediment, and/or groundwater that may contain with contaminants from historic uses. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

This impact focuses on the potential for soil disturbance and associated stockpiling and on-site soil movement during general site construction activities to create potential pathways through which fish and wildlife species could be exposed contaminants in HPS Phase II site soils. The potential for development of Project elements such as the Yosemite Slough bridge and shoreline improvements to disturb contaminated soils or sediment is evaluated separately in Impact HZ-9 and Impact HZ-10, respectively. Impact BI-4a, Impact BI-4b, and Impact BI-4c-in Section III.N describe potential biological resources impacts associated with development of specific Project shoreline improvements. Potential water quality impacts associated with shoreline improvements are evaluated in Impact HY-1a, Impact HY-1b, and Impact HY-1 in Section III.M.

Site preparation would include deep excavations for large structures such as residential towers, installation of foundation piles; trenching for utility lines; grading and compaction; and other earth-disturbing activities. These construction activities would involve grading, trenching, compacting, and excavating, which would result in soil and/or fill being handled, stockpiled, and moved on site.

Section III.N (Biological Resources) identifies the fish and wildlife species that could be affected by Project construction. These species include a broad range of resident and migratory fish and wildlife species. Common wildlife includes a number of species of invertebrates, reptiles and amphibians, birds, and mammals (terrestrial and aquatic). Common aquatic resources include many species of fish, shellfish, and mollusks.

As presented in the Setting, the results of comprehensive basewide and parcel-specific investigations have shown that chemicals and radioactive materials are present in soil and groundwater in various locations throughout HPS Phase II at levels that require remediation. The Navy has completed substantial investigation and remediation of the site, and the FFA Signatories overseeing the remediation program have required interim measures to be put in place in areas that still require remediation. Those measures include numerous actions to remove hazardous materials from soil and groundwater at the site, and the cleanup required by the regulatory agencies will continue to be implemented by the Navy regardless of whether or not the Project is implemented. However, full remediation of the entire HPS Phase II site is not anticipated for several years.

Further, as with many sites with former industrial uses, there is the potential to discover previously unidentified contamination or debris, even though all reasonable efforts have been implemented to identify such hazards. There have also been a number of investigations and actions to identify and remove subsurface structures (e.g., USTs, utility lines) at HPS Phase II and to manage identified contamination from those historic uses. Although these efforts have been extensive, the potential still exists for unidentified, old, or abandoned subsurface structures to be present at sites to be developed in HPS Phase II; in particular, it has not always been feasible to conduct physical investigation or comprehensive soil testing to determine the presence of USTs or the extent, if any, of soil contamination underneath existing buildings and structures.

As described previously, given the substantial amount of earthwork that would occur in HPS Phase II, there may be situations in which it may be feasible and more cost-effective to perform some soil remedial actions in conjunction with installation of utilities or other redevelopment activities in HPS Phase II. For example, the "Combined Plan for Candlestick Point and Hunters Point Shipyard" suggests that remediation work could be implemented at the proposed stadium site in Parcel G as part of site preparation.[337]

The primary environmental mechanisms for ecological exposure during soil disturbance would be (1) direct species contact with the fill or soil containing contaminants (e.g., birds landing on or rodents burrowing into stockpiled materials); (2) stormwater runoff from exposed soils or fill, or soils spilled onto roads during transport, which could carry contaminants into aquatic environments, where fish and benthic invertebrate species could be affected; or (3) windblown dust, which could be inhaled by terrestrial and avian species, or that could be deposited on surface water, where aquatic organisms could be affected.

[337] San Francisco Redevelopment Agency, Hunters Point Shipyard Preliminary Hazardous Materials Remediation Plan, http://www.hunterspointcommunity.com/docs/pdfs/Exhibit_D_Preliminary_Hazardous_Materials_Remediation_Plan.pdf (accessed July 2009).

There are controls and mitigation measures identified in this EIR that would reduce potential impacts on human populations, which would also help reduce the impact on ecological systems, as explained below. In addition, there are environmental conditions that would also reduce the potential for adverse impacts.

For example, the site mitigation plans prepared pursuant to Article 31-equivalent requirements, and risk management plans prepared pursuant to CERCLA documents (refer to Impact HZ-1b) would incorporate measures, such as covering stockpiles, which would minimize the potential for avian and terrestrial species to have direct contact with soil. Implementation of measures to control stormwater runoff during construction would control discharge of potential chemicals adhered to soil in the runoff. Mitigation measures MM HY-1a.1 and MM HY-1a.2 would require preparation of a SWPPP would be required to identify the specific measures and BMPs that are applicable to HPS Phase II construction activities in the event of a spill of construction materials or exposure of hazardous materials. This would reduce the likelihood of contaminants being conveyed to near-shore and offshore environments, which would reduce the risk to the aquatic environment and species that rely on that habitat (e.g., birds and mammals). Mitigation measure MM HZ-10b would also minimize the potential for sediments disturbed during shoreline improvements to pose a hazard to near-shore and aquatic species.

As explained in Impact HZ-10b, mitigation measures identified in Section III.N would also reduce impacts on ecological receptors. The general requirements of mitigation measures MM BI-4a.1 and MM BI-4a.2 (described in Section III.N) would reduce the effects of construction-related activities on aquatic habitat by requiring that appropriate permits be obtained from the USACE, SFRWQCB, BCDC, and other agencies as applicable (MM BI-4a.1) and implementing construction BMPs to reduce and/or prevent impacts to waters of the United States, including aquatic habitats (MM BI-4a.2). Mitigation measure MM BI-12b.1 identifies additional sediment management controls to reduce the effects of construction-related activities on aquatic species.

As described, dust control measures are required both by local ordinance and by BAAQMD. Implementation of dust control measures (mitigation measure MM HZ-15) would effectively reduce the potential for windborne dust that could affect fish and wildlife species. However, natural environmental conditions would also be a factor in minimizing the potential for contaminated dusts to adversely affect ecological systems. Avian species could be exposed to windblown dust through inhalation and ingestion during preening and prey consumption. Although various avian species use Candlestick Point for nesting and foraging, the mobility of the bird species results in their use of a relatively large home range and foraging range. Due to this mobility, avian species would not be present in one foraging area for an extended period of time in which they could receive substantial exposure to contaminants in dust. Windblown dust deposited onto water bodies could result in direct exposure to filter-feeding mollusks and other aquatic species. Additionally, excessive deposition of dust onto surface water, such as the Bay, could increase turbidity, which could, in turn, decrease light penetration into water and available oxygen. Even if dust control measures were not implemented, dusts generated by wind during construction would be dispersed over a relatively large area, with no single area receiving a sufficient volume of dust to generate a significant exposure to species.

Ponded water in open excavations and trenches (if contaminants were present and if standing water remained) could also present an ecological risk. However, because dewatering would be necessary to ensure proper construction conditions, groundwater would be removed routinely and frequently. Groundwater

would either be pumped into the sewage system or to the Bay in accordance with the Industrial Waste Ordinance of the *Public Works Code*. The sewage system is a closed system, with end of the line treatment, so there would be no direct exposure pathway to fish or wildlife. If shallow groundwater were to be pumped directly into the Bay as a necessary by-product of construction dewatering, the discharger would be required to notify and obtain approval of the RWQCB, as described in Section III.M (mitigation measure MM HY-1a.3). Any groundwater proposed for discharge from the Project site into the Bay must meet strict water quality standards established by the San Francisco Bay Basin Plan as defined by the RWQCB, and may have to be treated before discharge into the Bay to avoid potential degradation of the Bay's water quality. Furthermore, dischargers are required to meet stringent monitoring standards established by the RWQCB (and, as applicable, the State Water Resources Control Board) to ensure compliance under this permitting system. The requirements for construction dewatering would be specified in the ICs and RMPs for HPS Phase II. This would ensure potential aquatic impacts are minimized.

As explained in Impact HZ-10a, mitigation measures identified in Section III.N would also reduce impacts on ecological receptors. The general requirements of mitigation measures MM BI-4a.1 and MM BI-4a.2 (described in Section III.N) would reduce the effects of construction-related activities on aquatic habitat by requiring that appropriate permits be obtained from the USACE, SFRWQCB, BCDC, and other agencies as applicable (MM BI-4a.1) and implementing construction BMPs (MM BI-4a.2) to reduce and/or prevent impacts to waters of the United States, including aquatic habitats.

As described in Impact HZ-6b, restrictions on handling, stockpiling and transport of soil during construction activities at HPS Phase II will be a centerpiece of the legally-enforceable restrictions on uses and activities at the Project site described above (refer to the "Management of Hazardous Materials Contamination Risks During Development" section) and under which the Navy, USEPA, DTSC, RWQCB, and CDPH will, independent of this EIR, require to be in place before any Project development activity occurs at HPS Phase II.

Mitigation measures MM HZ-1a, MM HZ-1b, MM HZ-10b, and MM HZ-12 require construction activities require construction and grading activities and remediation activities conducted in conjunction with development at early transfer parcels to comply with all restrictions imposed pursuant to a CERCLA ROD, Petroleum Corrective Action Plan, FOST, FOSET FOSL, or an Administrative Order on Consent applicable to early transfer parcels, including restrictions imposed in Deeds, Covenants, Leases, and LIFOCs, and requirements set forth in Land Use Control Remedial Design Documents, and Risk Management Plans. Under the applicable requirements of CERCLA, RCRA, and the equivalent state cleanup requirements, ecological risk assessments have been conducted to determine the potential impact of hazardous material releases on ecological receptors such as fish and wildlife species as described in the current conditions discussion in this Section. Under CERCLA RCRA and the equivalent state cleanup requirements and other applicable laws and regulations, impacts to the environment, including impacts to ecological receptors such as fish and wildlife species, must be taken into account in establishing these restrictions applicable to actions that disturb known or potential contaminants in soil, sediment, or water.

The general requirements of mitigation measures MM HZ-1b, MM HZ-9, MM HZ-10b, and MM HZ-12 would require that activities be conducted only after approval of a workplan by the Navy, and if required, by the other FFA Signatories. This mitigation measure would also require activities be conducted in accordance with any other documents or plans required under applicable law or laws.

Compliance with the procedures described above would ensure that soil handling, stockpiling, and movement within HPS Phase II would not present a significant risk to the ecological environment. Therefore, with implementation of mitigation measures MM HZ-1a, MM HZ-1b, MM HZ-9, MM HZ-10b, MM HZ-12, MM HZ-15, MM HY-1a.1, MM HY-1a.2, MM HY-1a.3, MM BI-4a.1, MM BI-4a.2, and MM BI-12b.1, potential construction ecosystem impacts related to handling, stockpiling, and transport of contaminated soil (including shoreline sediments) and groundwater would be reduced to less-than-significant levels.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-14 **Construction activities associated with the Project would not expose ecological receptors to unacceptable levels of hazardous materials as a result of the disturbance of soil, sediment, and/or groundwater with contaminants from historic uses. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Site preparation would include deep excavations for large structures such as residential towers; installation of foundation piles; trenching for utility lines; grading and compaction; and other earth-disturbing activities. Additionally, there would be roadway improvements. These construction activities would involve grading, trenching, compacting, and excavating, which would disturb soil, sediment, and/or groundwater with potential contaminants from historic uses at levels that could expose ecological receptors (fish and wildlife species identified in Section III.N) to hazardous materials. With implementation of mitigation measures MM HZ-1a, MM HZ-1b, MM HZ-2a.1, MM HZ-9, MM HZ-10b, MM HZ-12, MM HY-1a.1, MM HY-1a.2, MM HY-1a.3, MM BI-4a.1, MM BI-4a.2, and MM BI-12b.1, potential construction ecosystem impacts related to handling, stockpiling, and transport of contaminated soil would be reduced to less-than-significant levels.

Impact HZ-15: Exposure to Naturally Occurring Asbestos

Impact HZ-15 **Construction and grading activities associated with the Project would not disturb soil or rock that could be a source of naturally occurring asbestos in a manner that would present a human health hazard. (Less than Significant with Mitigation) *[Criterion K.b]***

Background on Naturally Occurring Asbestos Issues in the Project Vicinity

As described above in the Setting section, asbestos is a naturally occurring mineral found in serpentinite rocks. There is no mapped serpentinite within Candlestick Point or locations to the west where proposed roadway improvements could be constructed. As shown in Figure III.L-1 in Section III.L, there is an area of serpentinite mapped in Parcel A, Parcel B, a portion of Parcel C, and a small area in Parcel G. Serpentinite may also underlie proposed roadway segment locations in that area. Previously disturbed serpentinite fragments have also been identified in fill material at HPS Phase II.

The 2000 Final EIR for HPS included a mitigation measure requiring various controls to be in place when working in areas with serpentinite, including complying with BAAQMD regulations.[338] Both to comply with BAAQMD requirements and local requirements in *San Francisco Health Code* Article 31, the Project Applicant of HPS Phase I prepared and implemented an Asbestos Dust Mitigation Plan (ADMP) and a DCP, respectively.

Community concern about the implementation of asbestos and dust control measures was heightened in Summer 2006 after the Phase I Project Applicant self-reported that its former asbestos air monitoring contractor had failed to ensure proper operation of the air monitoring stations for the first several months of grading activities and could not validate the sampling results. The SFDPH, the BAAQMD, USEPA, and independent experts from the University of California at San Francisco, along with the federal Centers for Disease Control (CDC) and the CDC Agency for Toxic Substances and Disease Registry (ATSDR) reviewed the potential health risks from construction dust containing asbestos in HPS Phase I.[339]. The reviews concluded that there was no significant health risk created by the grading activities at the Shipyard.[340] BAAQMD pursued enforcement action against the Project Applicant, who entered into a consent agreement to pay civil penalties for its air-monitoring contractor's failure to properly monitor and for its grading contractor's failure to fully implement components of the BAAQMD-approved asbestos dust-monitoring plan. The City also implemented a number of actions to enforce the requirements of its required DCP in order to minimize the potential for airborne asbestos during grading in HPS Phase I, including issuing several notices of violation requiring corrective action. Since then, the SFDPH has worked with the Project Applicant to improve the dust-monitoring program, and required preparation of a Revised DCP for HPS Phase I, which was implemented in February 2007. BAAQMD has also worked with the Project Applicant to improve the ADMP required by the state Airborne Asbestos Toxics Control Measure. Similarly, USEPA has worked with the Navy to ensure it is implementing asbestos dust control measures with respect to its remediation activities.

Types of Impacts and Control Measures for Naturally Occurring Asbestos

Naturally occurring asbestos is a potential health hazard. If large amounts are inhaled or swallowed over many years, it increases the risk that a person may develop cancer or other health problems. During grading in areas potentially containing naturally occurring asbestos, airborne asbestos could be released to the environment via air emissions that could present an inhalation or ingestion hazard to exposed populations.

---

338 San Francisco Redevelopment Agency and Planning Department, Final Environmental Impact Report, Hunters Point Shipyard Reuse, February 8, 2000. A copy of this document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

339 Compiled from various City correspondence and factsheets dated June 1, 2007, October 9, 2007; California Department of Public Health correspondence dated September 10, 2007; United States Environmental Protection Agency correspondence dated February 18, 2009; and US Department of Health and Human Services correspondence dated September 20, 2007. This correspondence is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

340 Compiled from various City correspondence and factsheets dated June 1, 2007, October 9, 2007; California Department of Public Health correspondence dated September 10, 2007; and US Department of Health and Human Services correspondence dated September 20, 2007. This correspondence is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

These emissions could result from the initial disturbance of previously undisturbed serpentinite, and from handling and/or spreading previously disturbed serpentinite fragments. Construction workers would be the most susceptible to potential risks. However, existing and future on-site and adjacent off-site populations (residents, tenants, visitors, and workers) could also be exposed to airborne asbestos if proper precautions were not fully implemented.

Construction activities disturbing less than one acre of rock containing naturally occurring asbestos in HPS Phase II where serpentinite is present would be required under BAAQMD regulations to implement specific dust mitigation before construction begins, and each measure must be maintained throughout the duration of construction. For construction activities disturbing one acre or greater of rock containing naturally occurring asbestos, BAAQMD requires construction contractors to prepare an ADMP, specifying measures that would be taken to ensure that no visible dust crosses the property boundary during construction. The ADMP must be submitted to and approved by the BAAQMD prior to the beginning of construction, and the site operator must ensure the implementation of all specified dust control measures throughout the construction Project.

Dust control measures would include: applying water during and after grading activities; covering stockpiles and truckloads; "track-out" prevention measures such as wheel washing stations at exits from the grading areas; placing final cover materials over any exposed naturally occurring asbestos at the end of the grading activities. In addition, depending on the location of the grading activity, it is possible that the BAAQMD may require air monitoring to determine if there is off-site migration of asbestos dust during construction activities, and may also require that activities temporarily shut down if the monitors detect specified levels of airborne asbestos.

In addition, the *San Francisco Health Code* Article 22B requires contractors to control dust (regardless of whether the construction activity is in an area with the potential for naturally occurring asbestos). Some of the dust control measures can include: controlling potential sources of emissions; implementing general dust control methods for traffic, grading, crushing, trenching and excavation, loading, stockpiles, foundation work, and post-construction stabilization of disturbed areas; demolition emissions control methods, monitoring and records, including corrective actions to control visible dust during active construction and times when no work is occurring. In addition, under the ordinance, projects over one half acre in size are required to submit a DCP to SFDPH for approval. Currently, a DCP for all areas of Parcel A HPS Phase I are required to be approved by SFDPH prior to grading pursuant to the current provisions of Article 31. Under Article 22B, SFDPH approval of DCPs are required at HPS Phase II prior to grading areas over one-half acre in size. When Article 31 is revised to encompass the remaining HPS parcels or an equivalent process is established then all areas of HPS Phase II will be required to submit a DCP. The DCPs may include installation of PM_{10} dust monitors and record keeping.

To reduce impacts related to asbestos exposure during construction activities, the following mitigation measure shall be implemented.

MM HZ-15 *Asbestos Dust Mitigation Plans and Dust Control Plans. Prior to obtaining a grading, excavation, site, building or other permit from the City that includes soil disturbance activities, the Project Applicant shall obtain approval of an Asbestos Dust Mitigation Plan (ADMP) from BAAQMD for areas over 1 acre that potentially contain naturally occurring asbestos and approval of a Dust Control Plan (DCP) from SFDPH for all areas at HPS Phase II and for areas over 0.5 acre at Candlestick Point. Compliance with the ADMP and DCP shall be required as a condition of the permit.*

The ADMP shall be submitted to and approved by the BAAQMD prior to the beginning of construction, and the Project Applicant must ensure the implementation of all specified dust control measures throughout the construction Project. The ADMP shall require compliance with the following specific control measures to the extent deemed necessary by the BAAQMD to meet its standard:

For construction activities disturbing less than one acre of rock containing naturally occurring asbestos, the following specific dust control measures must be implemented in accordance with the asbestos ATCM before construction begins and each measure must be maintained throughout the duration of the construction Project:

- *Limit construction vehicle speed at the work site to 15 miles per hour*
- *Sufficiently wet all ground surfaces prior to disturbance to prevent visible dust emissions from crossing the property line*
- *Keep all graded and excavated areas, around soil improvement operations, visibly dry unpaved roads, parking and staging areas wetted at least three times per shift daily with reclaimed water during construction to prevent visible dust emissions from crossing the property line. Increased watering frequency may be necessary whenever wind speeds exceed 15 miles per hour.*
- *Adequately wet all storage piles, treat with chemical dust suppressants, or cover piles when material is not being added to or removed from the pile*
- *Wash down all equipment before moving from the property onto a paved public road*
- *Clean all visible track out from the paved public road by street sweeping or a HEPA filter equipped vacuum device within 24 hours*

For construction activities disturbing greater than one acre of rock containing naturally occurring asbestos, construction contractors are required to prepare an ADMP specifying measures that will be taken to ensure that no visible dust crosses the property boundary during construction. The plan must specify the following measures, to the extent deemed necessary by the BAAQMD to meet its standard:

- *Prevent and control visible track out from the property onto adjacent paved roads. Sweep with reclaimed water at the end of each day if visible soil material is carried out from property.*
- *Ensure adequate wetting or covering of active storage piles*
- *Hydroseed or apply non-toxic soil stabilizers to disturbed surface areas and storage piles greater than ten cubic yards or 500 square feet of excavated materials, backfill material, import material, gravel, sand, road base, and soil that will remain inactive for seven days or more*
- *Control traffic on on-site unpaved roads, parking lots, and staging areas—including a maximum vehicle speed of 15 miles per hour or less*
- *Provide as much water as necessary to control dust (without creating run-off) in any area of land clearing, earth movement, excavation, drillings, and other dust-generating activity.*
- *Control dust emissions from off-site transport of naturally occurring asbestos containing materials*
- *Stabilize disturbed areas following construction*

If required by the BAAQMD, air monitoring shall be implemented to monitor for off-site migration of asbestos dust during construction activities, and appropriate protocols shall be established and implemented for notification of nearby schools, property owners, and residents when monitoring results indicate asbestos levels that have exceeded the standards set forth in the plan.

The DCP shall be submitted to and approved by the SFDPH prior to the beginning of construction, and the Project Applicant must ensure the implementation of all specified dust control measures

throughout the construction Project. The DCP shall require compliance with the following specific mitigation measures to the extent deemed necessary by the SFDPH to achieve no visible dust at the property boundary:

- *Submission of a map to the Director of Health showing all sensitive receptors within 1,000 feet of the site.*
- *Keep all graded and excavated areas, areas around soil improvement operations, visibly dry unpaved roads, parking and staging areas wetted at least three times per shift daily with reclaimed water during construction to prevent visible dust emissions from crossing the property line. Increased watering frequency may be necessary whenever wind speeds exceed 15 miles per hour.*
- *Analysis of wind direction and placement of upwind and downwind particulate dust monitors.*
- *Record keeping for particulate monitoring results.*
- *Requirements for shutdown conditions based on wind, dust migration, or if dust is contained within the property boundary but not controlled after a specified number of minutes.*
- *Establishing a hotline for surrounding community members who may be potentially affected by Project-related dust. Contact person shall respond and take corrective action within 48 hours. Post publicly visible signs around the site with the hotline number as well as the phone number of the BAAQMD and make sure the numbers are given to adjacent residents, schools, and businesses.*
- *Limiting the area subject to construction activities at any one time.*
- *Installing dust curtains and windbreaks on windward and downwind sides of the property lines, as necessary. Windbreaks on windward side should have no more than 50% air porosity.*
- *Limiting the amount of soil in trucks hauling soil around the job site to the size of the truck bed and securing with a tarpaulin or ensuring the soil contains adequate moisture to minimize or prevent dust generation during transportation.*
- *Enforcing a 15 mph speed limit for vehicles entering and exiting construction areas.*
- *Sweeping affected streets with water sweepers at the end of the day.*
- *Installing and using wheel washers to clean truck tires.*
- *Halting all construction activities during periods of sustained strong winds, hourly average wind speeds of 25 miles per hour.*
- *Applying soil stabilization methods to inactive areas.*
- *Sweeping off adjacent streets to reduce particulate emissions.*
- *Hiring an independent third party to conduct inspections for visible dust and keeping records of those inspections.*
- *Minimizing the amount of excavated material or waste materials stored at the site.*
- *Prevent visible track out from the property onto adjacent paved roads. Sweep with reclaimed water at the end of each day if visible soil material is carried out from property.*

For all areas, this measure shall be implemented through Article 22B (areas over one half acre) or for HPS Phase II through a requirement in the potential additions to Article 31 imposing requirements to parcels other than Parcel A or through an equivalent process established by the City or Agency.

Although the ADMP and DCP requirements described above would be required independent of this EIR, to ensure redundant protection, implementation of mitigation measure MM HZ-15 would require the preparation of an ADMP approved by BAAQMD and a DCP approved by SFDPH before commencing

grading activities and any other activity that could disturb potential sources of naturally-occurring asbestos (including Bay Fill areas with the potential to contain previously-disturbed serpentinite fragments). The mitigation measure would also require implementation of all the mitigation measures, and compliance with all the requirements, set forth in the ADMP and DCP. Implementation of this mitigation measure would reduce impacts related to naturally occurring asbestos exposure during construction activities to a less-than-significant level.

Impact HZ-16: Exposure to Hazardous Materials in Building and Structures

Impact of Candlestick Point

Impact HZ-16a **Construction at Candlestick Point would not result in a health hazard to construction workers, the public, or the environment as a result of the demolition or renovation of existing structures that could include asbestos-containing materials, lead-based paint, PCBs, or fluorescent lights containing mercury. (Less than Significant) *[Criterion K.b]***

The Project would include demolition of existing structures at Candlestick Point. Hazardous building materials are likely to be present in older structures including Candlestick Park stadium completed in 1960. Building materials could include asbestos-containing materials, lead-based paint, PCBs, and fluorescent lights containing mercury vapors. Demolition or renovation of existing structures could result in potential exposure of workers or the community to hazardous building materials during construction, without proper abatement procedures, and future building occupants could be exposed if hazardous building materials are left in place and not properly contained. Soil around a structure could also become contaminated by hazardous building materials if these materials were inadvertently released to the environment.

Inadvertent releases of friable asbestos, lead, or PCBs contained in materials or items removed during demolition activities could expose construction workers, occupants, or visitors to these hazardous materials, which could result in various adverse health effects if exposures were of sufficient quantity and length. In addition, some of the debris may meet criteria for hazardous waste and must be disposed of properly. To reduce potential human exposures to acceptable levels and to protect the environment, the Project would comply with several regulations and guidelines, discussed above, pertaining to abatement of and protection from exposure to asbestos and lead, as discussed under Section III.K.3, as appropriate (e.g., Cal/OSHA has regulations on worker exposure to both chemicals). Items containing PCBs, mercury, or other hazardous substances that are intended for disposal must be managed as hazardous waste and must be handled in accordance with OSHA worker protection requirements.

Implementation of applicable regulations and standards would ensure that potential health and environmental hazards associated with asbestos, lead, or PCBs in buildings and structures to be demolished would be minimized to the extent required by law. Therefore, impacts would be less than significant. No mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact HZ-16b **Construction at HPS Phase II would not result in a health hazard to construction workers, the public, or the environment as a result of the demolition or renovation of existing structures that could include asbestos-containing materials, lead-based paint, PCBs, or fluorescent lights containing mercury. (Less than Significant) *[Criterion K.b]***

Existing buildings in HPS Phase II would be demolished to accommodate new development. The potential hazards related to chemical contaminants in structures and facilities, and how those hazards would be managed to minimize the risk to human health and the environment would be as described for Candlestick Point. Further, any actions the Navy undertakes prior to or during development of the proposed land uses in HPS Phase II to abate hazardous building materials would also be subject to Navy procedures and reporting. Department of Defense policy states that all property containing asbestos will be conveyed, leased, or otherwise disposed of as-is through the BRAC process. Department of Defense policy regarding lead-based paint in existing residential areas is to manage it in a manner protective of human health and the environment, and to comply with all applicable laws and regulations. Pursuant to Department of Defense, Navy and USEPA policy, these deeds will contain restrictions that mandate compliance with certain federal policies and laws related to handling ACBM and lead.

The existing regulatory environmental framework and approval process would avoid potential hazards from demolition of buildings. Impacts would be less than significant. No mitigation is required.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-16 **Construction activities associated with the Project would not result in a health hazard to construction workers, the public, or the environment as a result of the demolition or renovation of existing structures that could include asbestos-containing materials, lead-based paint, PCBs, or fluorescent lights containing mercury. (Less than Significant) *[Criterion K.b]***

The Project would include demolition of existing structures at Candlestick Point and HPS Phase II. Building materials could include asbestos-containing materials, lead-based paint, PCBs, and fluorescent lights containing mercury vapors. Demolition or renovation of existing structures could result in potential exposure of workers or the community to hazardous building materials during construction, without proper abatement procedures, and future building occupants could be exposed if hazardous building materials are left in place and not properly contained. Implementation of applicable regulations and standards would ensure that potential health and environmental hazards associated with asbestos, lead, or PCBs in buildings and structures to be demolished would be minimized to the extent required by law. The existing regulatory environmental framework and approval process would avoid potential hazards from demolition. With the implementation of existing regulations, impacts would be less than significant. No mitigation is required.

Impact HZ-17: Worker Safety—Exposure to Hazardous Materials

Impact of Candlestick Point

Impact HZ-17a **Construction at Candlestick Point would not expose construction workers to unacceptable levels of hazardous materials in soil or groundwater in a manner which would present a human health risk. (Less than Significant with Mitigation) *[Criterion K.b]***

Potential worker health and safety impacts associated with site investigations, site remediation, underground storage tank removal, excavation, dewatering, and construction of improvements at locations in Candlestick Point could occur where these areas have been affected by hazardous materials. Such impacts would be minimized by implementing legally required health and safety precautions. For hazardous waste workers, federal and Cal/OSHA regulations mandate an initial training course and subsequent annual training. Site-specific training may also be required for some workers.

Although worker safety regulations would require the preparation and implementation of a site-specific HASP independent of this EIR, mitigation measure MM HZ-2a.2 would impose the requirement to prepare such a plan in compliance with applicable federal and state OSHA requirements and other applicable laws. The plan would include identification of chemicals of concern, potential hazards, personal protection clothing and devices, and emergency response procedures. Implementation of this mitigation measure would reduce impacts to less-than-significant levels.

Impact of Hunters Point Shipyard Phase II

Impact HZ-17b **Construction at HPS Phase II would not expose construction workers to unacceptable levels of hazardous materials in soil, sediment, or groundwater in a manner which would present a human health risk. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Potential worker health and safety impacts from exposure to hazardous materials could occur during excavation, dewatering, construction of improvements, site investigations, site remediation, and underground storage tank removal at HPS Phase II. The potential for these impacts to occur would be minimized by implementing legally required health and safety precautions. For workers at sites where they would encounter hazardous waste, federal and Cal/OSHA regulations mandate an initial training course and subsequent annual training. Site-specific training may also be required for some workers.

Although existing worker safety regulations would require preparation and implementation of a HASP independent of this EIR and work would be conducted in accordance with RMPs, to ensure compliance with these requirements, mitigation measure MM HZ-2a.2 would require a permit applicant to prepare, submit to SFDPH and implement a site-specific HASP for any affected location in compliance with applicable federal and state OSHA requirements and other applicable laws to minimize impacts to public health and the environment. The plan would include identification of chemicals of concern, potential hazards, personal protective equipment and devices, and emergency response procedures. Implementation of this mitigation measure would reduce impacts to less-than-significant levels.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-17 **Construction activities associated with the Project would not expose construction workers to unacceptable levels of hazardous materials in soil, sediment, or groundwater in a manner which would present a human health risk. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Potential worker health and safety impacts associated with site investigations, site remediation, underground storage tank removal, excavation, dewatering, and construction of improvements at locations in the Project site could occur where these areas have been affected by hazardous materials. Although worker safety regulations would require the preparation and implementation of a site-specific HASP independent of this EIR and work would be conducted in accordance with RMPs, mitigation measure MM HZ-2a.2 would impose the requirement to prepare such a plan in compliance with applicable federal and Cal/OSHA requirements and other applicable laws. The plan would include identification of chemicals of concern, potential hazards, personal protection clothing and devices, and emergency response procedures. Implementation of this mitigation measure would reduce impacts to less-than-significant levels.

Impact HZ-18: Construction Activities with Potential to Generate Hazardous Air Emissions within One-Quarter Mile of a School

Impact of Candlestick Point

Impact HZ-18a **Construction at Candlestick Point would not result in a human health risk involving the disturbance of naturally occurring asbestos, demolition of buildings that could contain hazardous substances in building materials, or possible disturbance of contaminated soils or groundwater within one-quarter mile of an existing school. (Less than Significant with Mitigation) *[Criterion K.c]***

The Bret Harte Elementary School is immediately west of Alice Griffith Public Housing site on Gilman Street and northwest of the proposed Candlestick Point North district (refer to Figure III.O-2 [Southeast San Francisco Schools and Libraries]).

As described under Impact HZ-17a, hazardous building materials are likely to be present in older structures within the Alice Griffith public housing site and could include asbestos-containing materials, lead-based paint, PCBs, and fluorescent lights containing mercury vapors. Demolition or renovation of existing structures could result in potential exposure of students, teachers, staff, and visitors at the school to hazardous building materials during construction, without proper abatement procedures. Soil around a structure could also become contaminated by hazardous building materials if these materials were released to the environment. To reduce the potential for the school site to be exposed to hazardous air emissions, the Project would comply with regulations and guidelines pertaining to abatement of and protection from exposure to asbestos and lead, as discussed under Section III.K.3 (Regulatory Framework) would be complied with, as appropriate. Implementation of applicable regulations and standards would ensure that hazardous air emissions from structures to be demolished would be minimized. Therefore, impacts would be less than significant, and no additional mitigation is required.

Some locations in Candlestick Point are known to contain low levels of contaminants in soil from historic uses; however, there are currently no sites within Candlestick Point requiring remediation. As explained in Impact AQ-3a, Impact AQ-3b, and Impact AQ-3 in Section III.H carcinogenic and noncarcinogenic health risks posed by contaminants bound to soil dust during construction activities associated with development of Candlestick Point would be below established thresholds. Therefore, the potential for contaminated dust to become airborne during construction that could cause hazardous emissions within is minimal. Nonetheless, if a contaminated site is identified during construction and testing under Article 22A, mitigation measure MM HZ-1a identified the location as requiring risk management, and if that location is within one-quarter mile of the school, the required Unknown Contaminant Contingency Plan (mitigation measure MM HZ-2a.1) would specify the necessary dust control requirements, and the Health and Safety Plan (mitigation measure MM HZ-2.a.2) would specify procedures to be protective of workers, which would also help minimize risks to off-site locations. This impact would be reduced to a less-than-significant level through implementation of Article 22A, where applicable, or mitigation measures MM HZ-1a, MM HZ-2a.1, and MM HZ-2a.2.

There are no rock formations containing naturally occurring asbestos in Candlestick Point, but there is fill material present that could contain rock fragments derived from locations elsewhere in the City in which asbestos could be present. This impact would be reduced to a less-than-significant level through implementation of mitigation measure MM HZ-15. Under MM HZ-15, construction activities disturbing less than one acre of rock containing naturally occurring asbestos would be required under BAAQMD regulations to implement specific dust mitigation before construction begins, and each measure must be maintained throughout the duration of construction. For construction activities disturbing one acre or greater of rock containing naturally occurring asbestos, BAAQMD requires construction contractors to prepare an ADMP, specifying measures that would be taken to ensure that no visible dust crosses the property boundary during construction. The ADMP must be submitted to and approved by the BAAQMD prior to the beginning of construction, and the site operator must ensure the implementation of all specified dust control measures throughout construction.

The school is more than one-quarter mile from portions of HPS Phase II, where there is known naturally occurring asbestos that could be disturbed and could be a source of airborne emissions (see below). However, mitigation measure MM HZ-15 is also required for construction in HPS Phase II, which would reduce impacts associated with development activities in HPS Phase II that, although unlikely, could affect locations in Candlestick Point.

Impact of Hunters Point Shipyard Phase II

Impact HZ-18b **Construction at HPS Phase II would not result in a human health risk involving the disturbance of naturally occurring asbestos, demolition of buildings that could contain hazardous substances in building materials, or possible disturbance of contaminated soils or groundwater within one-quarter mile of an existing school. (Less than Significant with Mitigation)** ***[Criterion K.c]***

Muhammad University of Islam, a year-round elementary school, is located adjacent to the Hillside portion of HPS Phase I development. No schools are proposed in HPS Phase II.

As shown in Figure III.L-1, there is an area of serpentinite mapped in Parcel A, Parcel B, a portion of Parcel C, and a small area in Parcel G. Serpentinite may also underlie proposed roadway segment locations in that area. Previously disturbed serpentinite fragments have also been identified in fill material at HPS Phase II. Therefore, construction within HPS Phase II would involve disturbance of naturally occurring asbestos, which could be a source of hazardous air emissions within one-quarter mile of a school.

An enhanced dust control program would be in place in accordance with the City's Dust Ordinance, which would be implemented under mitigation measure MM HZ-15. In addition, implementation of mitigation measures MM HZ-2a.1 and MM HZ-2a.2 for development in HPS Phase II would also help control dust emissions at HPS Phase II boundary, which would ensure airborne asbestos emissions do not present a health risk to the off-site school.

Demolition or renovation of existing structures in HPS Phase II could result in potential exposure of students, teachers, staff, and visitors at MUI to hazardous building materials during construction, without proper abatement procedures. Soil around a structure could also become contaminated by hazardous building materials if these materials were released to the environment. The Navy must adhere to regulations and guidelines pertaining to abatement of and protection from exposure to asbestos and lead, as discussed in Impact HZ-17b. Implementation of applicable regulations and standards would reduce impacts to a less-than-significant level. This would ensure that hazardous air emissions from structures to be demolished that could affect the school site would be minimized.

Construction activities in HPS Phase II would involve extensive construction to accommodate new development within that area. Site preparation activities could disturb known or previously unidentified contaminants in soil or groundwater that could be a source of hazardous emissions within one-quarter mile of MUI. However, as explained in Impact AQ-3a, Impact AQ-3b, and Impact AQ-3 in Section III.H (Air Quality), carcinogenic and noncarcinogenic health risks posed by contaminants bound to soil dust during construction activities associated with development of HPS Phase II would be below established thresholds. Nonetheless, because there would be hazardous emissions, this impact would be reduced to a less-than-significant level through implementation of mitigation measures MM HZ-1b, MM HZ-2a.1, MM HZ-2a.2, and MM HZ-15, as explained below.

For construction activities at HPS Phase II, mitigation measure MM HZ-1b would require SFDPH to verify, before all development activities at HPS Phase II that disturb soil or groundwater occur, that the activities would be done in compliance with all applicable restrictions pursuant to a CERCLA ROD, Petroleum Corrective Action Plan, FOST, FOSET or FOSL, or License Agreement, including restrictions imposed in deeds, covenants, leases, and LIFOCs, and requirements set forth in Land Use Control Remedial Design Documents, Risk Management Plans and health and safety plans. Implementation of those measures would ensure that potential adverse effects on the school site from exposure to known subsurface hazards from construction activities would be reduced to a less-than-significant level.

The disturbance of soil or groundwater containing previously unidentified contamination could also be a source of emissions that could affect the school site. If a previously unknown contaminated site is identified during construction, and if that location is within one-quarter mile of the school, the required Unknown Contaminant Contingency Plan (mitigation measure MM HZ-2a.1) would specify the necessary requirements and the dust control requirements required under a DCP (mitigation measure MM HZ-15)

and the Health and Safety Plan (mitigation measure MM HZ-2.a.2) would specify procedures to be protective of workers, which would also help minimize risks to off-site locations. This impact would be reduced to a less-than-significant level through implementation of mitigation measures MM HZ-1b, MM HZ-2a.1, MM HZ-2a.2, and MM HZ-15.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-18 **Construction activities associated with the Project would not result in a human health risk involving the disturbance of naturally occurring asbestos, demolition of buildings that could contain hazardous substances in building materials, or possible disturbance of contaminated soils or groundwater within one-quarter mile of an existing school. (Less than Significant with Mitigation) *[Criterion K.c]***

Construction within the Project site would involve disturbance of naturally occurring asbestos, demolition of buildings that could contain hazardous substances in building materials, and possible disturbance of contaminated soils or groundwater, each of which could be a source of hazardous air emissions within one-quarter mile of a school. The Bret Harte Elementary School is immediately west of Alice Griffith public housing site on Gilman Street and northwest of the proposed Candlestick Point North district. The Muhammad University of Islam is within one-quarter mile of HPS Phase II.

The results of a health risk assessment that evaluated the potential for contaminants bound to soil disturbed during construction are presented in Impact AQ-3a, Impact AQ-3b, and Impact AQ-3. The results indicate that carcinogenic and noncarcinogenic health risks posed by contaminants bound to soil dust during construction activities would be below established thresholds. Nonetheless, because hazardous air emissions could occur and could affect school sites, this impact at Candlestick Point would be reduced to a less-than-significant level through implementation of Article 22A, where applicable, or mitigation measures MM HZ-1a and MM HZ-2a.1. Implementation of mitigation measure MM HZ-1b would reduce impacts for HPS Phase II development. In addition, implementation of mitigation measures MM HZ-2a.1, MM HZ-2a.2, and MM HZ-15 would also help control dust emissions at the Project site boundary, which would ensure airborne asbestos emissions do not present a health risk off site.

Impact HZ-19: Potential Projectwide Impacts during Project Construction

Impact HZ-19 **Simultaneous construction activities at the Project site would not pose a human health risk from the release of contaminants from historic uses or fill. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

Construction impacts associated with the potential to encounter hazardous materials or hazardous conditions during construction anywhere in the Project site, whether at Candlestick Point or HPS Phase II would for the most part be site specific and not additive because development activities at one site would be localized and would not combine with activities at another site to create a greater, combined effect. In addition, development would be sequenced, so only portions of each area would be expected to be under development at the same time. For example, in the early stages of development, it is anticipated that on Candlestick Point, construction of replacement units for current residents of Alice Griffith public housing would occur first. On HPS Phase II, stadium construction is expected to begin first, followed by development of the mixed-use area planned in the Parcel B area. The Project would be sequenced as

- described in Chapter II and is anticipated to be complete by 2031. Some off-site roadway improvements would be done as part of the Project, but these would be of a limited nature, largely involving streetscape improvements and would be developed over time. On Candlestick Point and HPS Phase II, the development of both areas is expected to continue through approximately 2031, with only portions of each area under development at any one time.

One activity that could affect areas outside of the immediate work area is movement of soil from one location to another. The possible export of soil from off of the immediate construction site is discussed under Impact HZ-3a and Impact HZ-3b, and in Impact HZ-6a and Impact HZ-6b. As discussed in these sections, at Candlestick Point soil is expected to be reused within those areas or, if not hazardous waste and otherwise allowed under the environmental remediation program, to be reused at HPS Phase II. Soil excavated from Candlestick Point could be transported to and reused at HPS Phase II only if (1) the soil were not characterized as hazardous waste under state or federal hazardous waste management regulations; and (2) the soil were to comply with any applicable soil import requirements related to what type of soil can be placed into particular areas of the site, imposed as part of the remediation program overseen by the FFA Signatories and/or by a RMP and/or by local ordinance. Excavated soil removed at HPS Phase II may be used as fill elsewhere at HPS Phase II, to the extent permissible under the restrictions imposed through ICs and transfer documents (mitigation measure MM HZ-1b) and Navy-approved workplans (mitigation measure MM HZ-9). If nonhazardous soil is moved off site, it would be subject to laws concerning nonhazardous soil transport. Most soil is expected to remain in the Project site. However, if soil that is hazardous waste must be disposed of off site, the hauling and disposal would be subject to a number of existing environmental laws regulating these activities. If soils containing hazardous materials are allowed to be moved within a site, any movement would be subject to a variety of federal, state, and local environmental regulatory controls as detailed previously. Mitigation measures MM HZ-1a, MM HZ-1b, MM HZ-9, and MM HZ-15 would ensure that before development occurs within the Project site and vicinity that appropriate soil management plans and DCPs have been developed to address both soil movement and reuse within the Project site and off-site reuse and disposal. Under the mitigation measures, compliance with the requirements of these plans is a condition of development. With the implementation of these mitigation measures, impacts from soil movements within and outside of the entire Project site would be reduced to a less-than-significant level.

Impact HZ-20: Routine Use, Storage, Transportation, and Disposal of Hazardous Materials

Impact HZ-20 **Construction activities associated with the Project would not result in adverse impacts to construction workers, visitors, or the environment from the routine use, storage, transportation, and disposal of hazardous materials. (Less than Significant) *[Criterion K.a]***

Construction activities related to the proposed project would require the use and transportation of hazardous materials (e.g., fuels, cement products, lubricants, paints, adhesives, and solvents). In addition, construction vehicles would be used on-site that could accidentally release hazardous materials such as oils, grease or fuels. These hazardous materials and vehicles would remain on the Project site during the period of construction activities. Accidental releases of hazardous materials during demolition and construction activities could impact soil and/or groundwater quality, which could result in adverse health effects to construction workers,

the public, and the environment. However, the contractor's compliance with requirements related to DPH's HMUPA certificate of storage for hazardous materials during construction would reduce these potential impacts related to inadvertent release of hazardous materials to less-than-significant levels. In addition, the Project contractors would be required to comply with the requirements of Article 4.1 of the San Francisco Public Works Code, which requires preparation and implementation of a Stormwater Pollution Prevention Plan (SWPPP) (described in the Hydrology and Water Quality section), which would further reduce potential impacts related to inadvertent release of hazardous materials during construction.

Compliance with the SWPPP and HMUPA requirements would ensure that potential releases from the transport and use or disposal of hazardous materials during project construction activities would be reduced to a less-than-significant level. No mitigation is required.

Operational Impacts

After Project development and occupancy, operation of infrastructure and land uses could involve the use of products that could contain hazardous materials. In addition, maintenance activities could disturb site soils that contain hazardous materials.

Impact HZ-21: Routine Maintenance of Properties

Impact of Candlestick Point

Impact HZ-21a **Implementation of the Project at Candlestick Point would not result in adverse impacts to residents, visitors, or the environment from periodic maintenance requiring excavation of site soils to maintain or replace utilities, repair foundations, or make other subsurface repairs. (Less than Significant with Mitigation)** ***[Criteria K.b and K.d]***

After Project occupancy, it is likely that the City or others would from time to time need to excavate site soils to maintain or replace utilities, repair foundations, or make other subsurface repairs. Prior to occupancy, sites for which soil remediation would be necessary would either be remediated by excavation, in-situ treatment, or capping with impervious surfaces or pavement. Deed restrictions and covenants would indicate the depths to which clean fill has been placed. Therefore, contact with unremediated soil by construction workers, or inhalation of soils by workers or the public, would not be expected to pose a substantial human health risk. However, the restrictive covenants and any incorporated implementation documents would dictate the circumstances under which regulatory oversight agencies would allow work in unremediated soil and the conditions that would be attached to such work. In addition, implementation of mitigation measures MM HZ-1a, MM HZ-2a.1, and MM HZ-2a.2 would ensure risks to human health and the environment would be reduced to a less-than-significant level.

Impact of Hunters Point Shipyard Phase II

Impact HZ-21b **Implementation of the Project at HPS Phase II would not result in adverse impacts to residents, visitors, or the environment from periodic maintenance requiring excavation of site soils to maintain or replace utilities, repair foundations, or make other subsurface repairs. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

During occupancy, it is likely that the City or others would from time to time need to excavate site soils to maintain or replace utilities, repair foundations, or make other subsurface repairs. Prior to occupancy, sites for which soil remediation would be necessary would either be remediated by excavation, in-situ treatment, or capping with impervious surfaces or pavement. Deed restrictions and covenants would indicate the depths to which clean fill has been placed. Therefore, contact with unremediated soil by construction workers, or inhalation of soils by workers or the public, is not expected to pose a substantial human health risk. However, the restrictive covenants and any incorporated implementation documents would dictate the circumstances under which regulatory oversight agencies would allow work in unremediated soil and the conditions that would be attached to such work. This would ensure risks to human populations are minimized.

The proposed 300-slip marina along the east shoreline of HPS Phase II, north of the Gun Mole Pier would require creation of a 34-acre basin. The current water depths of the proposed basin are adequate for recreation craft. The basins would not require initial dredging, but maintenance dredging would be required in the future. The proposed marina is in Parcel F, adjacent to Parcel C; however, this area is not identified as an investigation/remediation subarea in which sediments are known to be contaminated

Implementation of mitigation measures MM HZ-1b, MM HZ-2a.1, MM HZ-2a.2, MM HZ-9, and MM HZ-12 would require compliance with restrictions set forth in ICs, transfer documents, and the AOC and requiring the preparation and implementation of a unknown contaminant contingency plan and HASP would ensure that impacts during occupancy from these routine maintenance activities would be reduced to a less-than-significant level.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HZ-21 **Implementation of the Project would not result in adverse impacts to residents, visitors, or the environment from periodic maintenance requiring excavation of site soils to maintain or replace utilities, repair foundations, or make other subsurface repairs. (Less than Significant with Mitigation) *[Criteria K.b and K.d]***

During occupancy, it is likely that the City or others would from time to time need to excavate site soils to maintain or replace utilities, repair foundations, or make other subsurface repairs. Prior to occupancy, sites for which soil remediation would be necessary would either be remediated by excavation, in-situ treatment, or capping with impervious surfaces or pavement. Deed restrictions and covenants would indicate the depths to which clean fill has been placed. Therefore, contact with unremediated soil by construction workers, or inhalation of soils by workers or the public, is not expected to pose a substantial human health risk. However, implementation of mitigation measures MM HZ-1a, MM HZ-1b, MM HZ-2a.1, MM HZ-2a.2, MM HZ-9, and MM HZ-12 would require compliance existing regulations and restrictions set forth in ICs, transfer documents, and the AOC and requiring the preparation and implementation of a

soil management contingency plan and HASP would ensure that impacts during occupancy from these routine maintenance activities would be reduced to a less-than-significant level.

Impact HZ-22: Routine Use, Storage, Transport, or Disposal of Hazardous Materials

Impact HZ-22 Implementation of the Project would not result in a significant impact involving the routine use, storage, transportation, and disposal of hazardous materials. (Less than Significant) *[Criterion K.a]*

Nearly all Project uses would involve the presence of hazardous materials (or products containing hazardous materials) at varying levels, and this would represent an increase in hazardous materials use compared to existing conditions. It would also increase the number people who could be exposed to potential health and safety risks associated with routine use. The following summarizes the general types of hazardous materials that would be expected in the Project, based on the proposed land use designations.

Households and certain businesses (e.g., retail stores, restaurants, hotel, entertainment venues, artists studios, office-based commercial businesses) would use relatively small quantities of hazardous materials. Typical products containing hazardous materials would consist mostly of household-type cleaning products as well as maintenance products (e.g., paints, solvents, cleaning products), fuels and other petroleum products, refrigerants associated with building mechanical and heating, ventilation and air conditioning (HVAC) systems, and some media used by artists. Grounds and landscape maintenance within the development area could also use a wide variety of commercial products formulated with hazardous materials, including fuels, cleaners and degreasers, solvents, paints, lubricants, adhesives, sealers, and pesticides/herbicides. Under the proposed stadium option, a similar range of maintenance products containing hazardous materials would routinely be used.

If cooling towers are used as part of stadium operations in conjunction with an air conditioning system, they may involve the use of a few chemicals to inhibit rust or corrosion in the storage units. However, the types and amounts would be limited, and their use would be subject to established laws and regulations.

The proposed R&D land uses are likely to include businesses and facilities supporting "green" technologies, in which some laboratory-based activities would be reasonably anticipated. Some R&D operations could involve "dry" laboratories (or operations), where relatively small or negligible quantities of hazardous materials would be used because the space would typically be used for office-based research, software development, and so on. In those cases, the types of hazardous materials would be limited to such items as cleaning and maintenance materials, and office products such as adhesives and glues. "Wet" research lab functions, on the other hand, could involve a broad spectrum of activities involving hazardous materials, which would be used in controlled environments (e.g., fume hoods and special rooms). The types and volumes of hazardous materials that would be used in wet research is difficult to predict because the specific businesses that could operate R&D facilities are not known, and because hazardous materials use is subject to continuous change as technologies evolve and as businesses change. However, it is reasonably foreseeable that hazardous materials would be used routinely. R&D businesses would be subject to more intense regulation and oversight than businesses (and households) that handle smaller quantities of more common materials. Employees performing wet laboratory work would be required (by law) to receive specific training, which is intended to protect the workplace as well as to minimize the potential

for spills or inadvertent releases that could adversely affect the environment through air emissions or releases to sewers, storm drains, or land.

Additionally, the types of hazardous materials that are typically used at marinas include fuel, oil, and maintenance products for boats. Therefore, underground fuel storage tanks and waste oil drums could be present at the Project site during operation of the marina.

If medical-related establishments (i.e., doctor/dentist offices, medical laboratories, or pharmacies) operate within the commercial areas of the Project site, small amounts of laboratory-type chemicals, compressed gases, pharmaceuticals, and radiological materials would be used and stored. Medical, biohazardous, and low-level radioactive wastes would be produced from these activities.

Wherever hazardous materials are used or stored, there is the potential for human exposure, and, under certain conditions, potential releases to the environment. In each situation, the potential hazards and the risks they would pose to people or the environment would depend on what materials would be used, where the materials would be used and stored, how they would be used, and who would use them. The routes through which these individuals could be exposed include inhalation, ingestion, dermal (skin and eye) contact, and other accidents.

For the Project, there are no large-scale manufacturing or processing facilities proposed that would store and use large quantities of hazardous materials that would present a substantial risk to people. However, there would be numerous locations where smaller quantities of hazardous materials would be present. The potential risks associated with hazardous materials handling and storage would generally be limited to the immediate area where the materials would be located, because this is where exposure would be most likely. For this reason, the individuals most at risk would be employees or others in the immediate vicinity of the hazardous materials, rather than residents or visitors. For the most part, the health and safety procedures that protect workers and other individuals in the immediate vicinity of hazardous materials would also protect the adjacent community and environment. The pathways through which the community or the environment (e.g., local air quality and biota) could be exposed to hazardous materials include air emissions, transport of hazardous materials to or from the site, waste disposal, human contact, and accidents. However, the only primary potential pathway for public exposure to hazardous materials would be airborne emissions under normal operations or upset conditions, such as those caused by diesel particular matter, toxic air contaminants, or traffic-related $PM_{2.5}$ emissions. These impacts are addressed in Section III.H in Impact AQ-2a, Impact AQ-2b, Impact AQ-2c, Impact AQ-2, Impact AQ-6, and Impact AQ-7.

Hazardous materials would routinely be transported to, from, and within the Project, and small amounts of hazardous waste would be removed and transported off site to licensed disposal facilities. The precise increase in the amount of hazardous materials transported to or from the Project site as a result of implementation of the Project cannot be definitively predicted due to the pending selection of tenants for the future retail-commercial stores. But it is reasonable to assume with the addition of new land uses involving hazardous materials use, there would be an increase in transportation relative to current conditions. Such transportation would be provided by vendors licensed for such transport, and appropriate documentation for all hazardous materials and wastes would be required for compliance with the existing hazardous materials regulations.

As indicated in the Regulatory Framework, there is an established, comprehensive framework independent of the CEQA process, which is intended to reduce the risks associated with hazardous materials use (and generation of hazardous waste). The San Francisco Department of Public Health (DPH), Hazardous Materials Unified Program Agency (HMUPA) has been granted authority by the State to enforce most regulations pertaining to hazardous materials in the City, including permitting for hazardous materials storage, underground storage tanks, and hazardous waste generation under the DPH Certificate of Registration Program.

Facilities where hazardous materials would be used during Project operation would be constructed in accordance with current laws and regulations, which require storage that minimizes exposure to people or the environment, and the potential for inadvertent releases. In addition, these materials would be labeled to inform users of potential risks and to instruct them in appropriate storage, handling, and disposal procedures. Employers are required by law (Cal/OSHA) to ensure employee safety by properly identifying hazardous materials and adequately training workers. The use of hazardous materials and generation of wastes would continue to be regulated under the authority of the DPH HMUPA under a compliance certificate, with additional oversight by other agencies (RHB, CDHS). Transporters of hazardous materials and wastes are required to comply with federal laws and regulations that are monitored and enforced by the CHP.

SFDPH HMUPA would continue to conduct periodic inspections to ensure that hazardous materials and wastes are being used and stored properly. For these reasons, hazardous materials uses and waste generation for project operations would not pose a substantial public health or safety hazard to the surrounding area. Impacts from the routine transport, use or disposal of hazardous materials (including radiological, hazardous and medical wastes) from operation of the proposed project would therefore be less than significant. No mitigation is required.

Impact HZ-23: Exposure to Hazardous Materials Via Upset and Accident Conditions

Impact HZ-23 **Implementation of the Project would not pose a human health risk and/or result in an adverse effect on the environment from reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment. (Less than Significant) *[Criterion K.a]***

Potential hazards from routine use, storage, transport, or disposal of hazardous materials are addressed in Impact HZ-22, above. Therefore, the following discussion focuses on risks to the public from exposure to accidental releases of hazardous materials through reasonably foreseeable upset and accident conditions during operation of the Project.

With increased routine use of hazardous materials compared to existing conditions, exposure of future occupants, visitors, and employees to hazardous materials could occur by improper handling or use of hazardous materials or hazardous wastes during operation of the Project, particularly by untrained personnel, environmentally unsound disposal methods, or fire, explosion, or other emergencies, all of which could result in adverse health effects. Accidents involving the transportation of hazardous materials to, from, or within the Project could also occur.

In general, the types and amounts of hazardous materials would not pose any greater risk of upset or accident compared to other similar development elsewhere in the City. No industrial manufacturing or processing activities using large amounts of hazardous materials or acutely hazardous materials, which typically pose a greater accident or upset risk, are proposed. Major hazardous materials accidents associated with retail-commercial uses, including restaurants, theaters, and stores are extremely infrequent. Moreover, as described in Impact HZ-22, releases, if any, present a greater, although manageable, risk to immediately exposed individuals rather than the population at large. The San Francisco Fire Department (SFFD) responds to hazardous materials incidents within the City, and additional emergency response capabilities are not anticipated to be necessary to respond to the potential incremental increase in the number of incidents that could result from operation of the Project.

Potential impacts from upset and accident conditions involving the release of hazardous materials and wastes would also be less than significant, because the project would be required to comply with DPH requirements for hazardous materials and waste management, which are described in Impact HZ-22, above. This includes preparation of required emergency response plans for facilities subject to HMBP requirements and permitting for hazardous materials storage, underground storage tanks, and hazardous waste generation under the DPH Certificate of Registration Program.

As described in the Section III.K.3 and as summarized in Impact HZ-22, the transportation of hazardous materials is required to comply with federal and state laws and regulations. These regulations identify proper labeling and packaging, transfer, and documentation requirements. State law prescribes requirements for through-transport of hazardous materials on roadways under state control.

There is a comprehensive and ongoing hazardous materials emergency response program in the city. San Francisco has an Emergency Response Plan (ERP) that was developed to ensure allocation of and coordination of resources in the event of an emergency in the City and County of San Francisco. The ERP describes at a high level what the City's actions will be during an emergency response.[341] A separate Hazard Mitigation Plan (HMP) assesses risks posed by natural and human-caused hazards and set forth a mitigation strategy for reducing the City's risks.[342] The specific departmental responsibilities for responding to hazardous materials incidents in the City are outlined in the "Emergency Support Function #10 Oil and Hazardous Materials Response Annex" to the ERP.[343] San Francisco Fire Department (SFFD) is the first responder in responding to hazardous materials emergencies for the city and county. This is less than significant. No mitigation is required.

Impact HZ-24: Facilities with Hazardous Air Emissions within One-Quarter Mile of a School

Impact HZ-24 **Areas designated for research and development uses within HPS Phase II would not pose a human health risk as a result of hazardous air emissions within one-quarter mile of a school. (Less than Significant with Mitigation)** ***[Criterion K.c]***

Impact AQ-6 in Section III.H, evaluates toxic air contaminant (TAC) emissions associated with R&D uses in HPS Phase II. The impact is summarized here as it relates to proximity to schools within one-quarter mile of the HPS Phase II site (Muhammad University of Islam). The reader is referred to Section III.I for detailed information about assumptions and analysis results.

For the purposes of the analysis in Impact AQ-6, a conservative scenario of potential TAC emissions from each potential future source of TACs was modeled to estimate the potential health impact on residential receptor locations within HPS Phase II. It was assumed that each allowable location for TAC emissions would emit chemicals at the maximum allowable rate, when, in fact, the TAC emissions at some of these locations within the R&D area would be below the maximum rate (for example, office building emissions for TAC would be zero or close to zero). Receptors evaluated in the analysis included (1) receptors on the boundary of each individual TAC emission source spaced 20 meters apart along the boundary ("boundary receptors") and (2) grid receptors placed over surrounding receptor locations, both on site (i.e., within the Project boundaries) and off site, spaced at 50 meters ("grid receptors").

The health risk assessment for R&D uses estimated the excess lifetime cancer risk and chronic noncancer hazard index resulting from the combined TAC emissions from the R&D areas at any surrounding receptor location within HPS Phase II. The estimated excess lifetime cancer risks and hazard indices within areas designated for residential use were found not to exceed the BAAQMD's current significance thresholds for carcinogenic and noncarcinogenic health risks with the Project.

Because BAAQMD's significance thresholds would not be exceeded for the most sensitive use within the Project (residential), the estimated numerical risk values would be further reduced, and thresholds would not be exceeded for off-site locations as well. In addition, mitigation measures MM AQ-6.1 and MM AQ-6.2 identify steps that would be taken to ensure numerical thresholds are not exceeded. Impacts would be less than significant for the MUI school site.

There are no potential sources of operational hazardous air emissions within Candlestick Point that could affect the Bret Harte Elementary School.

Impact HZ-25: Conflict with Airport Land Use Plans

Impact HZ-25 **The Project site is not within the San Francisco Airport Land Use Policy Plan and the Project would not result in a safety hazard for people residing or working in the Project site. (No Impact). *[Criterion K.e]***

The Project site is approximately six miles north of the San Francisco International Airport. The Project site is not located within any of the "restricted zones."[344] There would be no impact related to safety hazards for people residing or working in the Project site. No mitigation is required.

Impact HZ-26: Proximity to Private Air Strips

Impact HZ-26 **Implementation of the Project would not occur within the vicinity of a private airstrip and would not result in a safety hazard for people residing or working in the Project site. (No Impact). *[Criterion K.f]***

No private airstrips exist in the Project site or vicinity. There would be no impact related to safety hazards for people residing or working in the Project site. No mitigation is required.

Impact HZ-27: Fire Hazards, Emergency Response, and Evacuation Plans

Impact HZ-27 **Implementation of the Project would not expose people or structures to a significant risk of loss, injury, or death involving fires or conflict with emergency response or evacuation plans. (Less than Significant) *[Criteria K.g and K.h]***

Development of the Project would increase numbers of residents and employees in the Project site who, in turn, could result in congestion in the event of an emergency evacuation. San Francisco ensures fire safety primarily through provisions of the *San Francisco Building Code* and *San Francisco Fire Code*. Existing buildings are required to meet standards contained in these codes. In addition, the building plans for any new residential project greater than two units are reviewed by the SFFD and DBI in order to ensure conformance with these provisions. Project buildings and structures would be required to conform to these standards, which (depending on building type) may also include development of an emergency procedure manual and an exit drill plan.

In addition, hazardous materials are required to be stored in designated areas designed to prevent accidental release to the environment. And *Hazardous Materials Management Act* requires that businesses handling or storing certain amounts of hazardous materials prepare a Hazardous Materials Business Plan (HMBP), which includes an inventory of hazardous materials stored on site (above specified quantities), an emergency response plan, and an employee-training program. The information required under the HMBP is available to fire and hazardous materials incident responders. Facilities where hazardous materials would be used during Project operation would be constructed in accordance with current laws and regulations, which require storage that minimizes exposure to people or the environment, and the potential for inadvertent releases that would require emergency response. The use of hazardous materials and generation of wastes would continue

[344] City and County Associations of Governments of San Mateo County, San Mateo County Comprehensive Airport Land Use Plan: San Francisco International Airport Land Use Plan, December 1996.

to be regulated under the authority of the DPH HMUPA under a compliance certificate, with additional oversight by other agencies (RHB, CDHS). Transporters of hazardous materials and wastes are required to comply with federal laws and regulations that are monitored and enforced by the CHP.

The existing street grid provides ample access for emergency responders and egress for residents and workers, and the Project would neither directly nor indirectly alter that situation to any substantial degree. All new development at would be built to *San Francisco Fire Code* standards, which would help to minimize demand for future fire protection services. All development, including high-rise residential buildings up to forty stories, would meet standards for emergency access, sprinkler and other water systems, and other requirements specified in the *San Francisco Fire Code*. Standards pertaining to equipment access would also be met. Plan review for structures at Candlestick Point for compliance with *San Francisco Fire Code* requirements, to be completed by DBI and the SFFD, would minimize fire-related emergency dispatches, reducing the demand for fire protection services at the Project site. Therefore, the Project would not impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan. Finally, for the reasons just set forth, the Project would not directly or indirectly result in any additional exposure of residents or workers to fire risk, as the Project site is in a fully urbanized area that lacks the "urban-wildland interface" that tends to place new development at risk in undeveloped areas of California. The Project would also include expansion of the Auxiliary Water Supply System (AWSS), to provide water for firefighting services. Expansion of the AWSS would make the Project site more defensible against fire and reduce the need for fire protection services. Therefore, the Project would not expose people or structures to a significant risk of loss, injury, or death involving fires.

Compliance with the *San Francisco Building Code* and *San Francisco Fire Code* through the City's ongoing permit review process would ensure that potential fire hazards related to redevelopment activities (including those associated with hillside development, hydrant water pressure, and emergency access) would be minimized during the permit review process and that future projects would not interfere with an existing emergency response or emergency evacuation plan. Therefore, this impact would be less than significant. No mitigation is required.

Cumulative Impacts

Risks associated with hazardous materials impacts are generally localized and site-specific, with the exception of those resulting from transportation of hazardous materials. Since these risks are generally site-specific, the cumulative context for this analysis varies, depending on the threshold being analyzed. For example, cumulative impacts associated with the transportation of hazardous materials would be analyzed for projects along the transportation route, while the context for the use of hazardous materials would be limited to the area immediately surrounding the Project site. Cumulative impacts associated with the accidental release of hazardous materials into the environment would also be limited to the Project site and the immediately surrounding properties. Cumulative impacts associated with emergency response would be limited to development in the vicinity of emergency access routes. Cumulative impacts associated with air emissions are analyzed in Section III.H.

Routine Transport, Use, and Disposal of Hazardous Materials

The geographic context for the analysis of cumulative impacts related to the routine transport of hazardous materials is the major access routes for the Project, which would include Innes Avenue, Cargo Way, Evans Avenue, Arelious Walker Drive, portions of Jamestown Avenue, and Harney Way. Cumulative development in this geographic area would include all past and present development as generally described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable development in this area would consist of the Yosemite Slough Restoration Project, Executive Park, Jamestown, Hunters View, India Basin Shoreline, and Hunters Point Shipyard Phase I.

The cumulative context for an analysis of impacts related to use and disposal of hazardous materials would include all development in the Project vicinity, defined as the area bounded by US-101 on the west and south, the Islais Creek Channel on the north, and the Bay on the east. Cumulative development in this geographic area would include all past and present development as generally described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable development in this area would consist of the Yosemite Slough Restoration Project, Executive Park, Jamestown, Hunters View, India Basin Shoreline, and Hunters Point Shipyard Phase I.

Cumulative projects could result in generation of hazardous wastes such as asbestos from friable building materials, lead-based paint on building surfaces, and lighting fixtures. In addition, previously unknown contamination, possibly the result of improper disposal or housekeeping activities, may be discovered as structures are demolished. Cumulative development could expose construction workers to health or safety risks through exposure to hazardous materials, although the individual workers potentially affected would vary from project to project. At the state level, DTSC administers laws and regulations related to hazardous waste and hazardous substances pursuant to Division 20, Chapters 6.5 and 6.8 of the *California Health and Safety Code* and CCR Title 22, which are the state equivalents of RCRA and CERCLA, respectively. The RWQCB enforces laws and regulations governing releases of hazardous substances and petroleum pursuant to pursuant to Division 20, Chapters 6.7, 6.75, and 6.8 of the *California Health and Safety Code* (Sections 25100, 25200 and 25300 et seq.), and the *Porter Cologne Water Quality Control Act* (Division 7, Section 13100 et seq. of the *California Water Code*) and CCR Title 23. In particular, the RWQCB focuses on all petroleum releases and those hazardous substance releases that may impact groundwater or surface water. In addition, the CDPH is responsible for ensuring facilities that use, store, or dispose of radiological materials are properly investigated, decontaminated, and decommissioned or licensed (or properly issued an exemption from such requirements) in accordance with state and federal laws and regulations, including the state Radiation Control Law (*California Health and Safety Code* Section 114960 et seq. and CCR Title 17, Division 1, Chapter 5. These regulations have been in place for many years. Consequently many past projects have and all present and reasonably foreseeable future projects would be required to comply with applicable federal, state, and local regulations. Compliance with applicable regulations and guidelines pertaining to hazardous materials would ensure that cumulative impacts from construction activities would be less than significant.

The Project Description identifies proposed land uses, but the specific businesses or activities that could operate in the Project are not known at this time. The analysis assumes nearly all Project uses would involve the routine use of hazardous materials at varying levels and that there is the potential that such use could result in a release of hazardous materials. In each case, the potential hazards and the risks they would pose

to people or the environment would depend on what materials would be used, where the materials would be used and stored, how they would be used, and who would use them. Uses proposed under the Project would include R&D, for which a wide variety of hazardous materials would be used, facilities such as the proposed stadium, where fuels and maintenance products would comprise the majority of hazardous materials, and smaller-scale users, such as artists' studios and households, where only routine household types of chemicals would be used. Medical or dental offices could generate small quantities of medical waste that would be considered biohazardous, such as sharps, and would be required to comply with all code requirements related to disposal of these hazardous materials. No large-quantity waste generators would be developed as part of the Project. The Project would be required to comply with all local, state, and federal regulations pertaining to the use, handling, and disposal of hazardous materials.

Although existing, proposed, and reasonably foreseeable development could have potentially unique hazardous materials considerations, all such existing and potential users have and present and reasonably foreseeable future projects would comply with the range of federal, state, and local statutes and regulations applicable to the use, transport and disposal of hazardous materials, and would be required to comply with existing and future programs of enforcement by the appropriate regulatory agencies. Compliance with these federal, state, and local laws and regulations pertaining to hazardous materials management would be sufficient to minimize health and safety risks, because these laws and regulations have been designed to protect health and safety and are enforced by state and local agencies. For these reasons, potential cumulative impacts resulting from the use, transport, and disposal of hazardous materials would not be significant. Moreover, the Project would comply with all applicable statutes and regulations, which would ensure that the Project would not result in significant hazards as a result of hazardous materials use, transport, or disposal. Therefore, the Project's cumulative impact would be less than significant.

Reasonably Foreseeable Risk of Upset or Accident

The cumulative context for an analysis of impacts related to risk of upset or accident is the Project vicinity, defined as the area bounded by US-101 on the west and south, the Islais Creek Channel on the north, and the Bay on the east. Cumulative development in this geographic area would include all past and present development as generally described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable development in this area would consist of the Yosemite Slough Restoration Project, Executive Park, Jamestown, Hunters View, India Basin Shoreline, and Hunters Point Shipyard Phase I.

Cumulative development in this geographic area could handle or dispose of hazardous materials in such a way as to pose a risk from upset or accident. It is possible that cumulative development could expose residents and construction workers to contaminated soil or groundwater. There is known soil contamination at HPS, which would be remediated either by the Navy, as discussed above, or by the Project. Additional unknown soil or groundwater contamination could exist in the Project vicinity that could be released by development of the cumulative projects. *San Francisco Health Code* Article 22A, requires an investigation of the potential presence of hazardous wastes that may be present in soil within historic fill areas at construction sites as a prerequisite for certain building requirements. Such upsets or accidents, however, are likely to result in site-specific impacts and would not combine with another upset or accident that may occur on another site.

Hazardous waste may be generated from a site during construction and would need to be transported to a facility permitted to accept such waste. Management of specific hazardous wastes is addressed at the federal, state, and local levels. DTSC is authorized by USEPA to enforce the requirements of the federal RCRA. Under the state's Hazardous Waste Control Law, DTSC has adopted extensive regulations governing the generation, transportation, treatment, and disposal of hazardous wastes, which are more stringent than the requirements of RCRA. The state requirements for hazardous waste management specified in the *California Health and Safety Code*, Chapter 6.5, Article 2. The US DOT regulates hazardous materials transportation, including contaminated soil, between states, as described in Title 49 of the *Code of Federal Regulations*, and implemented by Title 13 of the CCR (California Vehicle Code). The California Highway Patrol and Caltrans are the state agencies with primary responsibility for enforcing federal and state regulations related to transportation within California.

Facilities where hazardous materials are used in the city must be constructed in compliance with current laws and regulations, which require hazardous materials storage that minimizes exposure to people or the environment, and the potential for inadvertent releases. In addition, these materials must be labeled to inform users of potential risks and to instruct them in appropriate storage, handling, and disposal procedures. Employers are required by law (Cal/OSHA) to ensure employee safety by properly identifying hazardous materials and adequately training workers. The use of hazardous materials and generation of wastes would continue to be regulated under the authority of the DPH HMUPA under a compliance certificate, with additional oversight by other agencies (RHB, CDHS). Transporters of hazardous materials and wastes are required to comply with federal laws and regulations that are monitored and enforced by the CHP. SFDPH HMUPA would continue to conduct periodic inspections throughout the City to ensure that hazardous materials and wastes are being used and stored properly. The City's

It is anticipated that all cumulative development projects would adhere to the applicable federal, state, and local laws and regulations that govern underground storage tanks and pesticide use, as well as requirements applicable to disposal and cleanup of contaminants. All cumulative projects would be required to comply with statutes and regulations pertaining to transport, use, handling, and disposal of hazardous materials, as noted, above. The regulatory schemes described above, however, include requirements for responding to such occurrences and ensuring that no health and safety impacts would result.

Cumulative projects could also affect the demand for hazardous materials emergency response services in the City, depending on the types of hazardous materials that would be handled. The likelihood of emergency incidents is more a function of the types of materials used as opposed to the quantities of materials used. Impacts on emergency services (fire, which includes hazmat response, and police) are analyzed in Section III.P (Public Services). The cumulative impact on emergency services was identified as less than significant.

All projects would be required to comply with applicable statutes and regulations, which would ensure that impacts related to the transport, use, and disposal of hazardous materials, would not be significant. Adherence to these regulations would also minimize the risk of upset or accident related to the handling of hazardous materials. For all of these reasons, potential cumulative impacts from the risk of upset or accident would not be significant. Additionally, mitigation measures for the Project have been included that would reduce the Project's impact related to risk of upset or accident to a less-than-significant level. Mitigation measures also require appropriate remediation of any site contamination. A site-specific

investigation would be conducted at locations where contaminated soils or groundwater could occur to minimize the exposure of workers to hazardous substances. The Project would be required to comply with all applicable codes and regulations to minimize or avoid risks from hazardous materials. As a result, the Project's cumulative impact would be less than significant.

Handling of Acutely Hazardous Materials within One-Quarter Mile of School

The geographic context for the analysis of this threshold is one-quarter mile of the schools that could be affected by the Project: the Bret Harte Elementary School and the private Muhammad University of Islam. No new schools are proposed within one-quarter mile of the Project. Development of cumulative projects could result in emissions of hazardous materials within one-quarter mile of these schools. As noted, above, hazardous materials are regulated through numerous codes and regulations, with oversight by various local, state, and federal agencies. These regulations are designed to ensure safety and human health. Risks associated with hazardous materials within one-quarter mile of an existing or proposed school would be eliminated or reduced through the requirements to comply with the handling, disposal practices, and/or cleanup procedures contained in these regulatory programs. Further, the Project's contribution to cumulative toxic air contaminant emissions would not exceed adopted BAAQMD thresholds (refer to Impact AQ-6 in Section III.H). Therefore, the Project's cumulative impact would be less than significant.

Hazardous Materials Release Sites

The cumulative context for an analysis of impacts related to hazardous materials sites is defined as the area bounded by US-101 on the west and south, the Islais Creek Channel on the north, and the Bay on the east. Cumulative development in this geographic area would include all past and present development as generally described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable development in this area would consist of the Yosemite Slough Restoration Project, Executive Park, Jamestown, Hunters View, India Basin Shoreline, and Hunters Point Shipyard Phase I.

Cumulative development in this geographic area may be located on or near a site included on a list of hazardous materials sites compiled pursuant to *Government Code* Section 65962.5. It is anticipated that future development would comply with applicable laws and regulations pertaining to hazardous wastes, and that risks associated with identified hazardous materials sites would be eliminated or reduced through compliance with the requirements for proper handling, disposal practices, and/or cleanup procedures. In many cases, development applications for projects affected by hazardous materials on identified sites would be denied by the City if adequate cleanup or treatment is not completed or feasible. Accordingly, cumulative impacts on the public or environment associated with development on or near hazardous materials sites would not be significant.

In June 2006, MACTEC conducted a Phase I Environmental Site Assessment (ESA) for Candlestick Point; in March 2009, MACTEC updated the assessment to include the proposed Candlestick Point Center, Alice Griffith housing development, the Jamestown Avenue parcels, and the CPSRA. No releases or areas of recognized environmental conditions were observed or noted during these Phase I assessments. The investigation report noted the presence of fill materials and a number of documented underground storage tanks (USTs) throughout Candlestick Point, some of which have been removed along with associated soil remediation. There may still be unknown USTs within Candlestick Point. No potentially significant impacts

from exposure to hazardous materials release sites were identified at the portions of Candlestick Point landward of the 1851 high-tide line (i.e., in bedrock areas and/or areas containing soil deposited by natural means), based on publicly available information. However, because there is a potential that previously unidentified (or unknown) contaminated sites could be encountered during development activities (either within the Project site or at off-site improvement locations), this EIR identifies mitigation measures consistent with applicable federal and state regulatory requirements to prevent those activities from adversely affecting human health and the environment.

As described previously, the historic uses at HPS by both the Navy and its tenants resulted in a number of hazardous materials release sites that are presently undergoing remediation by the Navy under federal law under the supervision of federal and state environmental agencies and in accordance with CERCLA. The Navy and regulatory agencies have determined that none of the areas that are accessible to tenants and visitors is a hazard to current tenants and visitors as determined in the 2008 Finding of Suitability to Lease (FOSL) issued by the Navy. All necessary remedial actions at HPS Phase II required by CERCLA, the FFA, or other applicable law must be completed to the satisfaction of the relevant regulatory agencies, and those agencies must determine that the site is suitable for its intended use, whether those remedial activities take place before or after the Navy transfers ownership of the property. The mitigation measures set forth in this section require the Project to be consistent with any requirements imposed as part of these remediation programs, and the federal, state, and local laws governing those remediation programs. Mitigation measures for the Project describe the required process if previously unidentified soil or groundwater contamination were encountered during construction or operation of the Project on any portion of the site and would ensure proper remediation in accordance with appropriate guidelines and applicable federal, state, and local laws and regulations. As a result, the Project's cumulative impact would be less than significant.

Impair Implementation of Adopted Emergency Response Plans

The geographic context for emergency response is the City and County of San Francisco. The City has an Emergency Response Plan (ERP) that was developed to ensure allocation of and coordination of resources in the event of an emergency in the City and County of San Francisco. Because the ERP is the planning document for the entire city and county, cumulative Project impacts are considered within that planning context.

The ERP describes at a high level what the City's actions will be during an emergency response. Forthcoming annexes and appendices to this plan will describe in more detail response actions and hazards specific to CCSF. While these additional plans are in development, existing departmental plans and hazard-specific annexes remain in effect. Further, this plan describes the role of the Emergency Operations Center (EOC) and the coordination that occurs between the EOC, City departments, and other response agencies. Finally, this plan describes how the EOC serves as the focal point between federal, state, and local governments in times of disaster.[345] A separate Hazard Mitigation Plan (HMP) assesses risks posed by natural and human-caused hazards and set forth a mitigation strategy for reducing the City's risks. Section 5.2.3.3 of the HMP describes the types, location, and probability of hazardous materials incidents.

[345] City and County of San Francisco, Emergency Response Plan, an Element of the CCSF Emergency Management Program, April 2008. A copy of this document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

The HMP reports, a hazardous materials event is most likely to occur within the City's industrial area, and along land and water transportation corridors. Trucks and vessels that use these transportation corridors commonly carry a variety of hazardous materials, including gasoline, other petroleum products, and other chemicals known to cause human health problems. The HMP also notes comprehensive information on the probability and magnitude of a hazardous material event along the transportation corridors is not available. Wide variations among the characteristics of hazardous material sources and among the materials themselves make such an evaluation difficult. However, based on previous occurrences, San Francisco can expect, on average, a hazardous material event every 4 years due to a truck accident and 7 times a year due to a large vessel accident as a result of equipment failure or operator error.[346]

The specific departmental responsibilities for responding to hazardous materials incidents in the City are outlined in the "Emergency Support Function #10 Oil and Hazardous Materials Response Annex" to the ERP.[347] San Francisco Fire Department (SFFD) is the first responder in responding to hazardous materials emergencies for the city and county.

San Francisco ensures fire safety primarily through provisions of the *San Francisco Building Code* and *San Francisco Fire Code*. Many existing buildings are required to meet standards contained in these codes. In addition, the building plans for any new residential project greater than two units are reviewed by the SFFD and DBI in order to ensure conformance with these provisions. All new development would be built to *San Francisco Fire Code* standards and required to meet standards for emergency access, sprinkler and other water systems, and other requirements specified in the *San Francisco Fire Code*. Project buildings and structures would be required to conform to these standards, which (depending on building type) may also include development of an emergency procedure manual and an exit drill plan. Plan review for structures at Candlestick Point for compliance with *San Francisco Fire Code* requirements, to be completed by DBI and the SFFD, would minimize fire-related hazardous materials emergency dispatches, reducing the demand for fire protection services at the Project site. Therefore, the Project would not impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan. Finally, for the reasons set forth above, neither the Project nor other cumulative development would directly or indirectly result in any additional exposure of residents or workers to fire risk, as the Project site and the surrounding area are fully urbanized and lack the "urban-wildland interface" that tends to place new development at risk in undeveloped areas of California. The Project would also include expansion of the Auxiliary Water Supply System (AWSS), to provide water for firefighting services. Expansion of the AWSS would make the Project site more defensible against fire and reduce the need for fire protection services. Compliance with the *San Francisco Building Code* and *San Francisco Fire Code* through the City's ongoing permit review process would ensure that potential fire hazards related to redevelopment activities (including those associated with hillside development, hydrant water pressure, and emergency access) would be minimized during the permit review process and that future projects would not interfere with an existing emergency

response or emergency evacuation plan. Therefore, because all cumulative development would be required to comply with applicable codes that would ensure effective implementation of the City's existing emergency plans, the Project's cumulative impact would be less than significant.

SECTION III.L GEOLOGY AND SOILS

III.L.1 Introduction

This section describes the geologic and seismic setting of the Project site, including regional and local geology, soils and groundwater, and the regulatory framework relevant to the Project. The potential environmental effects of the Project related to geology, soils, and seismicity are described. The impacts examined include risks related to geologic hazards such as earthquakes, landslides, liquefaction, expansive soils, and impacts on the environment related to soil erosion and sedimentation. This section identifies Project level and cumulative environmental impacts and explains how compliance with the applicable regulations, which are also identified as the mitigation measures, would reduce or avoid the identified impacts.

The Setting describes the local geologic setting and soils information for Candlestick Point (including the proposed Yosemite Slough bridge area) and for HPS Phase II. The EIR glossary, in Chapter VIII, defines unique terms used in the text below.

A preliminary geotechnical assessment of the Project site has been completed by ENGEO for Lennar Urban (refer to Appendix L [Geotechnical Report]).[348] The assessment is based on previous site-specific geotechnical and hazardous material investigations, some of which include subsurface borings, and review of published geologic reports and maps. This preliminary geotechnical assessment describes and evaluates geologic and geotechnical conditions at the Project site to support preliminary planning and conceptual-level design during initial phases of project planning. A design investigation to support preliminary infrastructure design efforts is underway at the time this EIR is being prepared. Design-level geotechnical studies would be completed on a parcel-by-parcel basis during development of construction plans.[349] Once infrastructure development is complete, foundation recommendations, which may or may not involve further exploration, would be required for each block. For high-rise structures, a unique foundation recommendation report would be required for each such building. The preliminary geotechnical assessment provides a summary and compilation of available geotechnical information that was used as part of the analysis of geologic, seismic, and geotechnical issues for this EIR.

III.L.2 Setting

The Project site is located in the southeastern area of San Francisco and extends east to San Francisco Bay (refer to Figure II-1 [Project Location]). This promontory is bounded on the south and west by the Bayview Hunters Point neighborhood and on the north and east by San Francisco Bay. The ground surface across the entire Project site is relatively flat with elevations ranging from approximately 0 feet to +20 feet (San

[348] ENGEO, Inc., *Preliminary Geotechnical Conceptual Design Report, Hunters Point Shipyard Phase II and Candlestick Point, San Francisco, California*, May 2009.
[349] ENGEO, 2009.

Francisco City Datum [SFCD]).[350] Maximum ground surface elevation near the Project site is on Bayview Hill (west of Candlestick Point), which reaches an elevation of approximately 400 feet SFCD.

Regional Geology

San Francisco Bay and the alluvial, colluvial, and estuarine deposits that underlie much of the Project site (and surrounding areas) occupy a structurally controlled basin in California's Coast Ranges province, which consists of 500 miles of northwest-trending ridges and valleys. Late Pleistocene and Holocene sediments (less than 1.0 million years old) were deposited in the basin as it subsided.[351] In the Project site, these sediments comprise estuarine deposits of Old Bay Clay, undifferentiated sedimentary deposits, Young Bay Mud, and alluvial/colluvial deposits, all of which rest on a variety of bedrock types associated with the Franciscan Complex. The Franciscan Complex makes up much of the basement rock of the Coast Ranges and consists of an assemblage of deformed and metamorphosed rock units. It formed in association with continuous east-dipping subduction at the margin of the North American and Pacific plates.[352] These two plates move relative to each other, with the San Andreas Fault Zone at the junction. The Pacific plate, on the west side of the fault zone, is moving north relative to the North American plate on the east.

Hunters Point Shear Zone

The Franciscan Complex north of Yosemite Slough is part of the Hunters Point shear zone, most of which is in the HPS Phase II site (refer to Figure III.L-1 [Geologic Map]). The Hunters Point shear zone consists of a shale matrix and serpentinite mélange that contains lenses of different lithologies (rock types). Regionally, the shear zone strikes northwestward and dips northeast at shallow to moderate angles.[353] The shear zone is thought to be part of a major structural zone marked by shallow bedrock that extends across the southeastern section of the San Francisco Peninsula, and southeast into the Bay. In the Project site, the southeastern margin of the shear zone extends from the Bay shoreline between Yosemite Slough and the southern base of Hunters Point in a northwest direction that intersects US-101 east of and adjacent to Islais Creek. The shear zone probably is not active, based on lack of offset of overlying sediments recorded by detailed seismic reflection studies.[354]

---

[350] San Francisco City Datum (SFCD) is a local vertical geodetic reference system specific to the City and County of San Francisco and formally established in 1964 as 8.616 feet above the National Geodetic Vertical Datum of 1929 (NGVD29), making it about 8.13 feet above mean sea level. The North American Vertical Datum was established in 1988 (NAVD88) and generally has replaced NGVD29 as a standard reference. Elevations expressed in NGVD29 may be converted to NAVD88 by adding 2.69 feet.

GEOLOGIC MAP

FIGURE III.L-1

The Franciscan Complex south of the Hunters Point shear zone is referred to as the Central terrane,[355] which is bound by the Hunters Point shear zone to the north and the City College fault zone, an inactive fault zone about one mile southwest of Candlestick Point, to the south (refer to Figure III.L-2 [Regional Fault Map]).[356]

Local Geology

Five soil and geologic units underlie the Project site. In general, basement units of the Franciscan Complex are covered by Quaternary sands, Bay Mud deposits, and artificial fill on the topographically low areas bordering San Francisco Bay.[357] The units are described from youngest to oldest, which approximates their vertical distribution from the top to the deeper units. Table III.L-1 (Summary of Geologic Conditions at Candlestick Point) and Table III.L-2 (Summary of Geologic Conditions at Hunters Point Shipyard Phase II) present general descriptions of the geologic units.

Table III.L-1 Summary of Geologic Units at Candlestick Point

Geologic Unit	*Map Symbol*	*Age*	*Lithology*
Artificial Fill	Qaf	Historic (0-200 years old)	Mixture of sand, gravel, and some clay. Abundant debris including wood, glass, and brick.
Slope Debris and Ravine Fill	Qsr	Holocene to Pleistocene (0-1.8 million years old)	Undifferentiated deposits of alluvium/colluvium consisting of clay to sandy clay, sandy silt, clayey to silty sand, clean sand, and silty gravel.
Bay Mud Deposits	Qm	Holocene to Pleistocene (0-1.8 million years old)	Highly compressible clay with minor layers of silt and clayey sand. Some shell fragments.
Undifferentiated Sedimentary Deposits	Qu	Holocene to Pleistocene (0-1.8 million years old)	Interbedded alluvial and marine deposits, light brown to yellowish brown, fine to medium grained, clean to clayey sand, and interbedded with stiff to very stiff, lean clay. Contains shell fragments. May contain some Colma Formation (Qc)
Franciscan Complex	KJs, KJc, KJg	Cretaceous to Jurassic (65 to 165 million years old)	Mixed assemblage of distinct bedrock types, including shale, chert, sandstone, and greenstone.

Artificial Fill (Qaf). Based on geotechnical borings, the Project site is blanketed with artificial fill, typically ranging in thickness from approximately 1 to 70 feet.[358] These deposits are thickest over closed depressions and gullies in the upper surface of the Bay Mud deposits (refer to discussion below), and thinnest over ridges in the Bay Mud surface.[359] Historical shoreline maps show artificial fill has been extended as far as 3,500 feet beyond the original shoreline in some areas around Candlestick Point and the HPS Phase II.[360] The fill lies on the Young Bay Mud, on competent alluvial/colluvial deposits, or on bedrock. In some instances, the weight of the fill created "mud waves" as the fill was placed on top of the soft Bay Mud surface. In this case, the process of fill placement pushed the soft Bay Mud beneath the fill out toward the Bay. This created deeper sections of fill where the Bay Mud was displaced beneath it.[361] The fill is primarily granular in nature, generally composed of excavated Franciscan Complex bedrock,[362] with the majority comprising a heterogeneous matrix of sand and gravel with varying amounts of clay and silt. The density of the fill is wide ranging, from loose to very dense granular materials and soft to stiff clays and silts. The artificial fill may include man-made debris such as wood, glass, brick, concrete blocks, and other industrial debris.[363] In the vicinity of the southeast-facing shoreline of Parcels D and E at HPS Phase II, it appears that a portion of the fill was constructed by placing dredged sand over Bay Mud. This fill consists of poorly graded (uniform) loose sands and its properties are inherently different than the fill elsewhere on site.

Slope Debris and Ravine Fill (Qsr). In the Project site, undifferentiated deposits of alluvium/colluvium occur primarily in areas immediately adjacent to bedrock exposures, at the base of slopes, and in accumulations in swales and gullies and are designated slope debris and ravine fill.[364] These deposits consist primarily of clay to sandy clay, sandy silt, clayey to silty sand, clean sand, and silty gravel.[365] These deposits include older colluvium that typically occurs between estuarine deposits and bedrock.

Bay Mud Deposits (Qm). Bay Mud is divided into younger and older deposits. Young Bay Mud underlies artificial fill in areas on which estuarine sediments were deposited and ranges in thickness from approximately 1 to 70 feet.[366] The Young Bay Mud consists predominantly of high plasticity clay with minor layers of lean to sandy clay, silt to clayey silt, and clayey sand, with some peat interbeds and lenses.[367] The Young Bay Mud typically is olive to dark greenish gray to blue gray, very soft to medium stiff, and contains abundant shell fragments.[368] The Young Bay Mud generally is normally consolidated and moderately to highly compressible. Where the Bay Mud has been further consolidated under the weight of fill, it has moderate shear strength. The Bay Mud thins to zero inland and thickens toward the Bay.[369] In some areas, where mud waves formed during placement of fill, the Bay Mud may be thicker or thinner than the original deposit. Locally, the deeper units of older Bay Mud, known as Old Bay Clay, are overconsolidated, and are composed of stiff to very stiff, silty to sandy clay, clayey silt, and clayey to silty sand.

Undifferentiated Sedimentary Deposits (Qu). These interbedded alluvial and marine deposits underlie younger Bay Mud deposits and overlie and interfinger with older Bay Mud deposits. Locally, they overlie basement rock directly.[370] Mostly composed of light brown to yellowish brown, fine to medium grained, poorly graded, medium dense to very dense, clean sand to clayey sand, these deposits are interbedded with stiff to very stiff, lean clay and contain some shell fragments.[371] Locally, these deposits may include sands of the Colma Formation (Qc).[372]

Franciscan Complex (KJ). The Franciscan Complex is a mixed assemblage of lithologically distinct rock types that are interbedded and tectonically disturbed.[373] The predominant Franciscan Complex rock types in the Project site are serpentinite, sandstone, chert, shale, and greenstone.[374] In the Project site, bedrock outcrops predominantly consist of chert, shale, and greenstone in the Candlestick Point site adjacent to the Bay and serpentinite, chert, sandstone, and shale in the HPS Phase II site.[375]

Soils

Soils at the Project site are imported fill material, and are derived from weathered materials and underlying rock or other natural deposits.[376] Soil types on the Project site were identified from soil survey data published by the US Department of Agriculture, Natural Resources Conservation Service.[377] The basic soil types mapped at the Project site are as follows:

- **Candlestick Point.** Candlestick Point site soils are predominantly "Urban land, Urban land—Orthents" (both cut & fill complex and reclaimed complex); Orthents soils in the low-lying areas; and Barnabe-Candlestick complex in the upland areas near Bayview Hill.
- **HPS Phase II.** HPS Phase II site soils are predominantly "Urban land, Orthents—cut and fill" and Urban land—Orthents (reclaimed complex).

Soil corrosivity against concrete and uncoated steel is moderate in the Barnabe-Candlestick complex soils. All the soil types at the Project site are interpreted to have a moderate corrosivity rating.[378]

A soil erosion hazard rating determines how likely it is that a soil will erode. Ratings are based on geology, topography, soil depth, vegetative cover, soil texture, and a climatic stress factor, which is a function of mean annual precipitation. Because of the variable nature of the deposits, all soil types at the Project site are interpreted to have a slight to severe erosion hazard rating.[379]

Consolidation Settlement of Young Bay Mud

Consolidation settlement occurs when a fine-grained soil (silt or clay) is loaded with the weight of new fill or of improvements such as structures or roads. New loads cause increases in soil pore water pressure. As the excess pore pressures dissipate, the soil volume decreases and water is expelled slowly. The rate of settlement depends on the permeability and thickness of the soil layers. Thick layers of clay with low permeability can take years for pore pressures to dissipate fully. It appears that most, if not all, the Young Bay Mud underlying the Project site is normally consolidated under the load of the existing fill and buildings. Placement of new fill to raise grades and construction of new buildings with shallow foundations in areas underlain by Young Bay Mud may trigger new consolidation settlement.

Compressible clays such as Young Bay Mud also exhibit secondary consolidation or compression as a function of the increased effective stress. The mechanism of secondary compression generally is thought to result from re-orientation of clay minerals under stress. Decomposition of organic content may be a factor in materials such as Young Bay Mud. Although settlement caused by secondary compression will decrease eventually, it will continue for an order of magnitude longer than primary consolidation. Continuing settlement caused by secondary compression in response to placing new fill is likely to be very small, except near the eastern shoreline of Candlestick Point where an area of deeper Young Bay Mud exists.

379 NRCS (accessed April 2008).

The deeper-lying Old Bay Clays are overconsolidated and will experience very small settlement as long as their maximum past pressure is not exceeded.

Slope Stability

Slope failures include many phenomena that involve the downslope displacement of material, triggered by static (i.e., gravity) or dynamic (i.e., earthquake) forces, such as landslides, rock-falls, debris slides, and soil creeps. Slope stability can depend on a number of complex variables, including the geology, structure, and amount of groundwater present, as well as external processes such as climate, topography, slope geometry, and human activity. Landslides and other slope failures may occur on slopes of 15 percent or less; however, the probability is greater on steeper slopes that exhibit old landslide features such as scarps, slanted vegetation, and offset surfaces.

- **Candlestick Point.** Potential landslide hazards at the Candlestick Point site are presented in Figure III.L-3 (Seismic Hazard Map). The figure shows that the major landslide hazard area at the Project site is an approximate 2,500-foot-wide and 2,500-foot-long section above Jamestown Avenue, east of US-101 and west of Candlestick Point State Recreation Area (CPSRA).
- **HPS Phase II.** A few smaller landslide hazards existed in a large serpentinite block of the Hunters Point Shear Zone, between Innes and Crisp Roads, northwest of the HPS Phase II site (refer to Figure III.L-3).[380] However, slopes adjacent to HPS Phase II have been rebuilt as subdrained engineered slopes as part of on-going HPS Phase I development. Remaining potential landslide hazard areas are outside of HPS Phase II site boundaries.

Groundwater Levels

Groundwater levels in the artificial fill and the underlying estuarine deposits generally are less than 15 feet below the ground surface and experience varying degrees of tidal fluctuation. In the upland or hilly areas, seasonally influenced groundwater occurs in artificial fill and alluvium/colluvium (slope/ravine deposits) at wide ranging depths below the ground surface.[381] Historically, depths to groundwater in the undifferentiated sedimentary deposits have been measured as shallow as three feet in the lowland areas and as deep as 30 feet below ground surface in the upland areas.[382]

SEISMIC HAZARD MAP

FIGURE III.L-3

Faulting and Seismic Hazards

Regional Seismicity

The San Francisco Bay Area is in a seismically active region near the boundary between two major tectonic plates, the Pacific Plate to the southwest and the North American Plate to the northeast. Since approximately 23 million years ago, about 200 miles of right-lateral slip has occurred along the San Andreas Fault Zone to accommodate the relative movement between these two plates. The relative movement between the Pacific Plate and the North American Plate generally occurs across a 50-mile zone extending from the San Gregorio Fault in the southwest to the Great Valley Thrust Belt to the northeast. In addition to the right lateral slip movement between tectonic plates, a compressional component of relative movement has developed between the Pacific Plate and a smaller segment of the North American Plate at the latitude of San Francisco Bay during the last 3.5 million years.[383] Strain produced by the relative motions of these plates is relieved by right lateral strike slip faulting on the San Andreas and related faults, and by vertical reverse-slip displacement on the Great Valley and other thrust faults in the central California area.[384]

The San Francisco Bay Area and surrounding areas are characterized by numerous geologically young faults. Figure III.L-2 (Regional Fault Map) illustrates the fault locations in relation to the Project site. These faults can be classified as historically active, active, sufficiently active, or inactive, as defined below.[385]

- Faults that have generated earthquakes accompanied by surface rupture during historic time (approximately the last 200 years) and faults that exhibit a seismic fault creep defined as **historically active**.[386]
- Faults that show geologic evidence of movement within Holocene time (approximately the last 11,000 years) are defined as **active**.
- Faults that show geologic evidence of movement during the Holocene along one or more of their segments or branches and if their traces may be identified by direct or indirect methods are defined as **sufficiently active** and **well defined**.
- Faults that show direct geologic evidence of inactivity or lack of offset, during all of Quaternary time or longer are classified as **inactive**.

The California Geological Survey (CGS) does not attempt to quantify the probability that an earthquake will occur on any specific fault, but this classification is based on the reasonable assumption that if a fault has moved during the last 11,000 years, it is likely to produce earthquakes in the future.

Groundshaking

An earthquake is classified by the amount of energy released, which traditionally has been quantified using the Richter scale. Recently, seismologists have begun using a moment magnitude (M) scale because it provides a more accurate measurement of the size of major and great earthquakes. For earthquakes of less

384 A "reverse-slip" fault is one with predominantly vertical movement in which the upper block moves upward in relation to the lower block.

385 CGS, *Fault Rupture Hazard Zones in California*, CDMG Special Publication 42, 2007, p.5.

386 Fault creep is movement along a fault that does not entail earthquake activity.

than M 7.0, the moment and Richter magnitude scales are nearly identical. For earthquake magnitudes greater than M 7.0, readings on the moment magnitude scale are slightly higher than a corresponding Richter magnitude.

The intensity of the seismic shaking, or strong ground motion, during an earthquake is dependent on the distance and direction between a particular area and the epicenter of the earthquake, the magnitude of the earthquake, and the geologic conditions underlying and surrounding that area. Earthquakes occurring on faults closest to the Project site probably would generate the largest ground motions.

A review of historic earthquake activity from 1800 to 2005 indicates that 13 earthquakes of magnitude M 6.0 or greater have occurred in the vicinity of the Project site during this time frame. The two most consequential were the earthquakes of April 18, 1906 and October 17, 1989. The April 18, 1906 earthquake caused building collapses and fires, approximately 3,000 deaths, and $524 million in damage as far as 350 miles from the epicenter. The earthquake of October 17, 1989 caused 63 deaths, more than 3,000 injuries, and an estimated $6 billion in property damage from San Francisco to Monterey and in the East Bay, including damage and destruction of buildings, roads, bridges, and freeways. There have been 25 earthquakes with magnitudes between M 5.5 and M 6.0 in this area during this time period, including numerous aftershocks of larger earthquakes.[387]

The intensity of earthquake-induced ground motions can be described using peak ground accelerations, represented as a fraction of the acceleration of gravity (g).[388] The interactive CGS Probabilistic Seismic Hazard Assessment map provides data to estimate peak ground accelerations in California.[389] Taking into consideration the uncertainties regarding the size and location of earthquakes and the resulting ground motions that can affect a particular site, the map depicts peak ground accelerations with a 10 percent probability of being exceeded in 50 years, which equals an annual probability of 1 in 475 of being exceeded in any given year. The CGS Probabilistic Seismic Hazard Assessment map accounts for amplification. Amplification effects can occur when seismic waves travel through soft soils underlain by shallow bedrock.

Fault Rupture

Faults are geologic zones of weakness. Surface rupture occurs when movement on a fault deep in the earth breaks through to the ground surface. Surface ruptures associated with the 1906 San Francisco earthquake extended for more than 260 miles with displacements of up to 21 feet. Not all earthquakes result in surface rupture. The 1989 Loma Prieta earthquake caused major damage in the San Francisco Bay Area, but the fault trace does not appear to have broken at the ground surface.

Fault rupture almost always follows preexisting faults, which are zones of weakness. Rupture may occur suddenly during an earthquake or slowly in the form of fault creep. Sudden displacements are more damaging to structures because they are accompanied by shaking.

Liquefaction

Liquefaction is a phenomenon in which saturated granular, non-plastic sediments temporarily lose their shear strength during periods of strong groundshaking, such as that which occurs during earthquakes. Seismic waves traveling through soils can cause deformations that collapse the loose granular structure. This collapse of void space in turn can cause an increase in pore water pressure, reducing the effective stress between the grains. When the pore pressures reach a critical level at which the effective stress of the soil drops below the overburden stress, the previously solid granular soil loses the strength to support itself and may behave like a viscous fluid. Secondary effects associated with liquefaction include flow failures, which occur when liquefied soil moves down a steep slope with large displacement and much internal disruption of material. Soil may also lose its ability to support structures, and this loss of bearing strength may cause structures founded on the liquefied materials to tilt or possibly topple over. Light structures such as pipelines, sewers, and empty fuel tanks that are buried in the ground can float to the surface when they are surrounded by liquefied soil. The susceptibility of a site to liquefaction is a function of the uniformity, depth, density, and water content of the granular sediments beneath the site and the magnitude of earthquakes likely to affect the site.

The vast majority of liquefaction hazards are associated with sandy soils and silty soils of low plasticity. Cohesive soils generally are not considered susceptible to soil liquefaction. In addition to sandy and silty soils, some gravelly soils are potentially vulnerable to liquefaction. Most gravelly soils drain relatively well, but when their voids are filled with finer particles or they are surrounded by less pervious soils, drainage can be impeded and they may be vulnerable to cyclic pore pressure generation and liquefaction. In general, liquefaction hazards are most severe in the first 50 feet below the ground surface, but on a slope near a free face or where deep foundations go beyond that depth, liquefaction potential should be considered for greater depths. There are two general levels of liquefaction hazards: (1) large-scale displacement and (2) localized failures including lateral spreading, vertical settlement from densification, sand boils, ground oscillation, flow failures, loss of bearing strength, and buoyancy effects, as described below.

Lateral Spreading

Lateral spreading is a phenomenon where large blocks of intact, nonliquefied soil move downslope riding on a liquefied substrate of large extent[390]. The mass moves toward an unconfined area, such as a descending slope or stream-cut bluff, and can occur on slope gradients as gentle as one degree.

Earthquake-Induced Settlement

Settlement or subsidence of the ground surface can be accelerated and accentuated by earthquakes. During an earthquake, settlement can occur as a result of the relatively rapid rearrangement, compaction, and settling of subsurface materials (particularly loose, uncompacted, and variable sandy sediments). Settlement can occur both uniformly and differentially (i.e., where adjoining areas settle at different rates). Localized

[390] Youd, T., et al., "Mapping liquefaction induced ground failure potential", in Proceedings of American Society of Civil Engineers, Journal of the Geotechnical Engineering Division, 1978; Tinsley, J., et al., Evaluating Liquefaction Potential. In *Evaluating Earthquake Hazards in the Los Angeles Region—an Earth Science Perspective*, USGS professional paper 1360, 1985, p. 263-315.

differential settlements up to two-thirds of the total settlements anticipated must be assumed until more precise predictions of differential settlements can be made.

Sand Boils

Sand boils occur when localized pore pressures increase to a level greater than the overburden pressure. If there is no pathway for dissipation of the excess pore pressures, the liquefied material may travel upward, following the path of a vertical fracture or zone of weakness. Sand-laden water can be ejected from a buried liquefied layer and erupt at the surface to form sand volcanoes. The surrounding ground often fractures and settles in the vicinity of the sand boil.

Ground Oscillation

During ground oscillation, the surface layer, riding on a buried liquefied layer, is thrown back and forth by the shaking and can be severely deformed.

Seismic Slope Instability/Ground Cracking

Earthquake motions can induce substantial stresses in slopes, causing earthquake-induced landslides or ground cracking when the slope fails. Earthquake-induced landslides can occur in areas with steep slopes that are susceptible to strong ground motion during an earthquake. The 1989 Loma Prieta earthquake triggered thousands of landslides over an area of 770 square miles.

Site Seismicity and Local Seismic Hazards

Table III.L-3 (Active Bay Area Faults) lists fault data for major faults within 30 miles of the Project site. The fault data shown in Table III.L-3 are based on the 2002 Revised California Fault Parameters by the CGS.[391] The closest fault to the Project site is the Peninsula branch of the San Andreas Fault, approximately 6.6 miles to the west.

Fault Rupture

No known active faults cross the Project site, making hazards from fault rupture unlikely. The Hunters Point Shear Zone, which crosses the HPS Phase II site in the northwest, is considered inactive, as is the City College Fault Zone about one mile southwest of Candlestick Point (refer to Figure III.L-1).[392]

- **Amplification**

Amplification effects can occur when seismic waves travel through soft soils underlain by shallow bedrock. During the design-level, site-specific seismic hazards assessment, appropriate attenuation relationships will be selected to account for amplification effects. All structures and improvements will be designed based on the appropriate seismic design parameters recommended in the seismic hazards assessment required by mitigation measure MM GE-4a.1.

Table III.L-3 Active Bay Area Faults

Fault Name (Branch)	*Distance from miles (km)*	*Fault Length (km)*	*Maximum Earthquake Magnitude (M)*
San Andreas (Peninsula)	6.6 (10.7)	85	7.1
San Gregorio (North)	10.7 (17.2)	110	7.2
San Andreas (North Coast South)	10.8 (17.4)	190	7.4
Hayward (South)	12.0 (19.3)	53	6.7
Hayward (North)	12.4 (20.0)	35	6.4
Monte Vista—Shannon	21.3 (34.3)	45	6.7
Calaveras (North)	21.6 (34.7)	45	6.8
Rodgers Creek	25.2 (40.6)	62	7.0

SOURCE: California Geological Survey, 2002
M = Moment Magnitude, which is directly related to average fault slip and rupture area.

Liquefaction

Holocene-aged alluvial sediments are especially prone to liquefaction. The Project site is in an area of San Francisco that has been designated as potentially liquefiable. As depicted in Figure III.L-1, the majority of the Project site is covered by lowland soils and artificial fill, which is the most susceptible soil layer for liquefaction. The granular materials in the heterogeneous fill typically are loose and saturated beneath the shallow groundwater table, and may liquefy when subjected to groundshaking, resulting in loss of soil strength, settlement, and lateral spreading. Because of the heterogeneous nature of the fill, liquefaction is expected to occur in random layers and pockets, limiting the extent of seismically induced settlement and lateral spreading to localized zones within the fill. The hydraulically placed sand fill in the vicinity of the southeast-facing shoreline of Parcels D and E at HPS Phase II consists of a thick unit of predominantly uniform sand and is, therefore, more susceptible to liquefaction.

- Based on existing data, there is little or no risk of large translational movements.[393,394] Design-level liquefaction studies, which are further described in mitigation measures MM GE-5a, would address five general types of localized potential hazards, and provide treatment methods, including the following:
  - Potential foundation bearing failure, or large foundation settlements caused by ground softening and near-failure in bearing
  - Potential structural and/or site settlements
  - Localized lateral displacement; "lateral spreading" and/or lateral compression
  - Flotation of light structures with basements, or underground storage structures
  - Hazards to Lifelines (utilities critical to emergency response)

[393] ENGEO, 2009.
[394] Engineering/Remediation Resources Group, Inc. and Shaw Environmental, Inc., *Remedial Investigation/Feasibility Study Report for Parcel E-2, Hunters Point Shipyard, San Francisco, California*, February 2009.

Lateral Spreading

Historical soil borings indicate that materials with the potential for lateral spreading are present in the artificial fill near the free face of the Yosemite Slough shoreline.[395] In addition, the area of hydraulically placed sand fill in the vicinity of the southeast-facing shoreline of Parcels D and E at HPS Phase II has higher than usual susceptibility to lateral spreading.

Earthquake-Induced Settlement

Areas are susceptible to differential settlement if underlain by compressible sediments, such as poorly engineered artificial fill or Bay Mud. Seismically induced settlements at the Project site will vary considerably because of the heterogeneous nature of the fill. It is estimated that settlement between one to two percent of the zones susceptible to liquefaction, or approximately two to twelve inches, may occur at the site during strong groundshaking. If untreated, structures supported on shallow foundations in areas susceptible to settlement may experience one or more of the following:

- Damaging differential settlement, tilt and possibly be subject to localized bearing capacity failures
- Abrupt differential settlement between unimproved ground and pile-supported improvements
- Differential settlement of buried utilities and disruption of flow gradients
- Damage to non-flexible surface improvements

Treatments to correct settlement hazards are available using options described in mitigation measure MM GE-4. It is common to use several methods in combination to correct settlement hazards, depending on the magnitude of the geotechnical hazard present and the types of structures proposed. Where treatment would be necessary and implemented, total and differential seismic settlement would be reduced to acceptable levels for the types of structures and foundation support conditions encountered, as required by the *San Francisco Building Code*.

Sand Boils

Because of the heterogeneous nature of the fill, liquefaction is expected to occur in random layers and pockets on the Project site, limiting the extent of seismically induced sand boils to localized areas within the fill. The hydraulically placed sand fill in the vicinity of the southeast-facing shoreline of Parcels D and E at HPS Phase II consists of a thick unit of predominantly uniform sand and is, therefore, more susceptible to liquefaction. The mitigation measures to reduce liquefaction and other seismic hazards would also reduce the risk of formation or sand boils during a seismic event.

Ground Oscillation

During ground oscillation, the surface layer, riding on a buried liquefied layer, is thrown back and forth by the shaking and can be severely deformed. While the soils at the Project site have been identified as potentially liquefiable, there is no evidence of a broadly spanning buried liquefiable layer on which the surface layer could be oscillated. The mitigation measures to reduce liquefaction and other seismic hazards would also reduce the risk of damage to structures from deformation by ground oscillation during a seismic event.

[395] GTC, *Preliminary Foundation Report: Griffith Bridge and Walker Bridge*, Bayview Transportation Improvements Project, San Francisco, CA, 2008.

Seismic Slope Instability/Ground Cracking

Hazards associated with seismically induced mudslides, rockslides, or landslides are not anticipated because of the relatively flat topography of the Project site and the surrounding vicinity.[396]

III.L.3 Regulatory Framework

Protection of geologic resources and reduction of geologic hazards are governed by state and local jurisdictions. Seismic hazards are addressed by state and local requirements for identifying and avoiding faults and the effects of seismic groundshaking when considering new development. Federal standards, such as those promulgated through the National Earthquake Hazards Reduction Program (NEHRP), apply to new federally owned, constructed, or assisted buildings. The following acts, codes, and local plans are relevant to geologic and seismic issues in the Project site.

Federal

Executive Order 12699

Executive Order 12699, "Seismic Safety of Federal and Federally Assisted or Regulated New Building Construction," was signed by President George H. W. Bush on January 5, 1990, to further the goals of Public Law 95-124, the *Earthquake Hazards Reduction Act of 1977*, as amended. The Executive Order applies to new construction of buildings owned, leased, constructed, assisted, or regulated by the federal government. Guidelines and procedures for implementing the order were prepared in 1992 by the federal Interagency Committee on Seismic Safety in Construction. The guidelines establish minimum acceptable seismic safety standards, provide evaluation procedures for determining the adequacy of local building codes, and recommend implementation procedures. Each federal agency is independently responsible for ensuring appropriate seismic design and construction standards are applied to new construction under its jurisdiction.[397]

Under the original Executive Order 12699, the model code for the West Coast was the Uniform Building Code developed by the International Conference of Building Officials (ICBO). In 1994, the ICBO joined with other similar organizations in the Southeast and on the East Coast to form the International Code Council (ICC). In 2000, the ICC published the first International Building Code (IBC) based on the reassessment of earlier codes and the combined updated experience of ICC member organizations. The current 2006 IBC is the result of nearly 100 years of building code improvement and forms the basis of the California and San Francisco building codes (discussed below), which are successively more stringent than the codes in force at the time of the implementation of the original federal guidelines.

State

Alquist-Priolo Earthquake Fault Zoning Act

Surface rupture is the most easily avoided seismic hazard. The *Alquist-Priolo Earthquake Fault Zoning Act* was passed in 1972 to mitigate the hazard of surface faulting to structures for human occupancy. In accordance with this act, the State Geologist established regulatory zones, called "earthquake fault zones," around the surface traces of active faults and published maps showing these zones. Buildings for human occupancy are not permitted to be constructed across the surface trace of active faults. Each earthquake fault zone extends approximately 200 to 500 feet on either side of the mapped fault trace, because many active faults are complex and consist of more than one branch. There is the potential for ground surface rupture along any of the branches. The Project site is not in an Alquist-Priolo Earthquake Fault Zone. Therefore, the Project would not be subject to this Act.

Seismic Hazard Mapping Act

The state regulations protecting the public from geo-seismic hazards, other than surface faulting, are contained in California *Public Resources Code* Division 2, Chapter 7.8 (the *Seismic Hazards Mapping Act*), described here, and 2007 *California Code of Regulations* (CCR), Title 24, Part 2 (the *California Building Code* [CBC]), described below. Both of these regulations apply to public buildings, and a large percentage of private buildings, intended for human occupancy.

The *Seismic Hazard Mapping Act* was passed in 1990 following the Loma Prieta earthquake to reduce threats to public health and safety and to minimize property damage caused by earthquakes. The Act directs the CGS to identify and map areas prone to the earthquake hazards of liquefaction, earthquake-induced landslides, and amplified groundshaking. The Act requires site-specific geotechnical investigations to identify potential seismic hazards and formulate corrective measures prior to permitting most developments designed for human occupancy within the Zones of Required Investigation.

As of February 2009, 117 official seismic hazard zone maps showing areas prone to liquefaction and landslides had been published in California, and more are scheduled for 2010. The mapping is being performed in Southern California and San Francisco Bay Area. Twenty-seven official maps for San Francisco Bay Area have been released, with preparation of additional maps for San Mateo, Santa Clara, Alameda, and Contra Costa Counties planned or in progress. The Project site is on the Seismic Hazard Map for the City and County of San Francisco (Hunters Point Quadrangle), published in November 2001, and shows approximately 90 percent of the Project site to be in a Zone of Required Investigation for liquefaction potential. Although past earthquakes have caused ground failures in only a small percentage of the total area in mapped hazard zones, a worst-case scenario of a major earthquake during or shortly after a period of heavy rainfall has not occurred in Northern California since 1906.[398]

Section 2697 of the Seismic Hazards Mapping Act mandates that, prior to the approval of a project in a seismic hazard zone, the City must require the preparation of a geotechnical report defining and delineating any seismic hazard. CGS has published Special Publication 117A, *Guidelines for Evaluating and Mitigating*

[398] California Geological Survey, *Guidelines for Evaluating and Mitigating Seismic Hazards in California*, CGS Special Publication 117A, 2008, p. 9.

Seismic Hazards in California, to assist the engineering geologist and/or civil engineer who must investigate the site and recommend mitigation of identified earthquake-related hazards and to promote uniform and effective statewide implementation of the evaluation and mitigation elements of the Seismic Hazards Mapping Act. Under the act, the San Francisco Department of Building Inspection (DBI), the local permitting authority, must regulate certain development projects within the mapped hazard zones. For projects in a hazard zone, DBI requires that the geologic and soil conditions of the Project site are investigated and appropriate mitigation measures, if any, incorporated into development plans. "Mitigation" is defined as those measures that are consistent with established practice and reduce seismic risk to acceptable levels.[399] "Acceptable level" of risk is defined as that level that provides reasonable protection of public safety, although it does not necessarily ensure continued structural integrity and functionality of a building.[400] Based on the above definitions of mitigation and acceptable risk, the *Seismic Hazards Mapping Act* and related regulations establish a statewide minimum public safety standard for mitigation of earthquake hazards. That standard is the minimum level of mitigation for a project that would reduce the risk of ground failure during an earthquake to a level that does not cause the collapse of buildings for human occupancy, but in most cases, not to a level at which no ground failure would occur.

The Act and associated regulations state that the site-investigation reports must be reviewed by a certified engineering geologist or registered civil engineer with competence in the field of seismic hazard evaluation and mitigation. As required by the mitigation measures herein, DBI would employ a third-party engineering geologist and/or civil engineer to form a Geotechnical Peer Review Committee (GPRC) which would complete the technical review. After a site investigation report was approved, subsequent site investigation reports would not be required, provided that new geologic information warranting further investigation was not recorded. The *San Francisco Building Code* requires that the recommendations of the report be incorporated in the building design.

The City is required to submit one copy of the approved site investigation report to the State Geologist within 30 days of approval. If the City approves a project that is not in accordance with the policies and criteria of the *Seismic Hazards Mapping Act*, the City is required to explain in writing the reasons for the differences to the State Geologist, within 30 days of the project's approval. The site-specific geotechnical investigation may refine the State's areawide interpretations. If the new documentation supports the site-specific interpretation, the State Geologist would file the report as an amendment to the Seismic Hazard Evaluation for the appropriate United States Geological Survey (USGS) topographic quadrangle map.

[399] *Public Resources Code*, Section 2693(c).
[400] *California Code of Regulations,* Title 14, Section 3721(a).

Caltrans Bridge Design Specifications and San Francisco Department of Public Works Standard Specifications

State guidelines protecting bridges and overpasses on state roads from geologic and seismic hazards are contained in Caltrans *Bridge Design Specifications*,[401] *Bridge Memo to Designers*,[402] *Bridge Design Practice Manual*,[403] and *Bridge Design Aids Manual*.[404] The manuals provide state-of-the-art information to address geo-seismic issues that affect the design of transportation infrastructure in California. Bridge design is required to be based on the "Load Factor Design methodology with HS20-44 live loading (a procedure to incorporate the estimated weight of the vehicles and/or pedestrians on the bridge with the weight of the bridge for loading calculations)" in the *Bridge Design Specifications*. Seismic-resistant design is required to conform to the *Bridge Design Specifications* and Section 20 of *Bridge Memo to Designers*, as well as Caltrans *Seismic Design Criteria*.[405] Section 20 of *Bridge Memo to Designers* outlines the category and classification, seismic performance criteria, seismic design philosophy and approach, seismic demands and capacities on structural components, and seismic design practices that collectively make up Caltrans' seismic design methodology. The methodology applies to all bridges and highways designed in California. A bridge's category and classification determines its seismic performance level and which methods would be used to estimate the seismic demands and structural capacities. The performance criteria include functional and safety evaluations of ground motion, level of service to be attained following a major earthquake, and the level of damage the structure must be designed to withstand.

The Caltrans *Seismic Design Criteria* specify the minimum seismic design requirements that are necessary to meet the performance goals established in Section 20 of *Bridge Memo to Designers*. Each bridge presents a unique set of design challenges and the *Seismic Design Criteria* provide guidelines to determine the appropriate methods and level of refinement necessary to design and analyze each bridge on a case-by-case basis. The Caltrans Offices of Structures Design provide the bridge designer with resources to establish the correct course of action and Senior Seismic Specialists, an Earthquake Committee, and an Earthquake Engineering Office of Structure Design Services and Earthquake Engineering to peer-review proposed methods and provide further recommendations.

[405] Caltrans, Division of Engineering Services, *Seismic Design Criteria, version 1.4*, 2009. http://www.dot.ca.gov/hq/esc/techpubs/manual/othermanual/other-engin-manual/seismic-design-criteria/sdc.htm>, last updated August 7, 2008 (accessed June 17, 2009).

The San Francisco Department of Public Works Bureau of Engineering (BOE) Standard Specifications for Streets and Highways,[406] and for Structures[407] are based on the Caltrans design specifications and provide detailed information regarding materials and procedures for road and bridge construction in the City. The BOE provides design and inspection services for City streets, infrastructure, and structures. During the construction phase, BOE would be responsible for assuring that the Project would be consistent with applicable codes, standards, and principles as implemented by the Project contractor.

California Building Code and the San Francisco Building Code

Until January 1, 2008, the *California Building Code* (CBC) was based on the then current *Uniform Building Code* and contained Additions, Amendments and Repeals specific to building conditions and structural requirements in California. The 2007 CBC, effective January 1, 2008, is based on the current (2006) *International Building Code* (IBC).[408] Each jurisdiction in California may adopt its own building code based on the 2007 CBC. Local codes are permitted to be more stringent than Title 24, but, at a minimum, are required to meet all state standards and enforce the regulations of the 2007 CBC beginning January 1, 2008.

San Francisco adopted the 2007 CBC as the basis for its Building Code (*Municipal Code* Title 17, Chapter 17.04) through Ordinance No. 3789, on December 3, 2007. The full 2007 San Francisco Building Code (SFBC) consists of the 2006 IBC, as amended by the 2007 CBC, and as further modified by San Francisco amendments designed to be used in conjunction with the 2007 CBC. The SFBC amendments were adopted by the Board of Supervisors on November 6, 2007, through Ordinance 258-07, effective January 1, 2008.

Chapter 16 of the SFBC deals with structural design requirements governing seismically resistant construction (Section 1604), including (but not limited to) factors and coefficients used to establish seismic site class and seismic occupancy category for the soil/rock at the building location and the proposed building design (Sections 1613.5 and 1613.6). Chapter 18 of the SFBC includes (but is not limited to) the requirements for foundation and soil investigations (Section 1802); excavation, grading, and fill (Section 1803); allowable load-bearing values of soils (Section 1804); and the design of footings, foundations, and slope clearances (Section 1805), retaining walls (Section 1806), and pier, pile, driven, and cast-in-place foundation support systems (Section 1808, 1809 & 1810). Chapter 33 of the SFBC includes (but is not limited to) requirements for safeguards at work sites to ensure stable excavations and cut or fill slopes (Section 3304). Appendix J of the SFBC includes (but is not limited to) grading requirements for the design of excavations and fills (Sections J103 through J107) and for erosion control (Sections J109 & J110).

Compliance with the SFBC is mandatory for development in San Francisco. Throughout the permitting, design, and construction phases of a building project, Planning Department staff, DBI engineers, and DBI building inspectors confirm that the SFBC is being implemented by project architects, engineers, and contractors.

---

[406] San Francisco Department of Public Works' Bureau of Engineering, *Standard Specifications—Part 2, Streets and Highways*. http://www.sfgov.org/site/uploadedfiles/sfdpw/boe/ Part2-StreetsAndHighways.pdf, 2000-09, last updated not provided (accessed June 17, 2009).

[407] San Francisco Department of Public Works' Bureau of Engineering, *Standard Specifications—Part 4, Structures*. http://www.sfgov.org/site/uploadedfiles/sfdpw/boe/Part4-Structures.pdf, 2000-09, last updated not provided (accessed June 17, 2009).

[408] California Building Standards Commission, *2007 California Building Code*, California Code of Regulations, Title 24, Part 2, Volumes 1 and 2, effective January 1, 2008.

During the design phase for buildings in the Project, foundation support and structural specifications based on the preliminary foundation investigations would be prepared by the Project engineer and architect and would be reviewed for compliance with the SFBC by the Planning Department and DBI.

During the Project construction phase, DBI inspectors would be responsible for enforcing the provisions of the SFBC as implemented by the contractor.

San Francisco General Plan

The City of San Francisco *General Plan* (1996) provides long-term guidance and policies maintaining and improving the quality of life and the man-made and natural resources of the community. The Community Safety Element includes policies for the avoidance of geologic hazards and/or the protection of unique geologic features. The plan requires detailed site-specific geologic hazard assessments in areas delineated with geologic hazards (seismic hazards, landslides, and liquefaction). Filled land and geologic hazards, such as landslides and shoreline erosion, are addressed in the Environmental Protection Element of the City of San Francisco *General Plan*. The Element includes policies for the promotion of the highest standards of soils engineering, the correction of landslide and shore erosion conditions, and the avoidance of construction on land subject to slide or erosion.

San Francisco Bay Plan

The San Francisco Bay Conservation and Development Commission (BCDC) is a federally designated state coastal management agency for San Francisco Bay. Bay shoreline construction projects, such as filling or dredging in the Bay, certain tributaries to the Bay, salt ponds, and managed wetlands around the Bay, or grading within 100 feet of the Bay shoreline, require permit approval from the BCDC. The BCDC issues an Administrative Permit for minor repairs or improvements along the Bay shoreline and a Major Permit for more extensive projects along the Bay shoreline. The Project would involve the construction of a marina, a bridge across Yosemite Slough, and various shoreline improvements. Such activities would require a permit from BCDC.

In accordance with *McAteer-Petris Act of 1965*, the BCDC is responsible for maintaining and carrying out the policies of the *San Francisco Bay Plan* (Bay Plan). The Bay Plan, adopted in 1969 and more recently amended in 2008, specifies goals, objectives and policies for existing and proposed waterfront land uses use and other BCDC jurisdictions areas. Part III of the Bay Plan contains findings and policies pertinent to the development of the Project.

III.L.4 Impacts

■ Significance Criteria

The City and Agency have not formally adopted significance standards for impacts related to geology and soils, but generally consider that implementation of the Project would have significant impacts if it were to:

L.a Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:

i. Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on

other substantial evidence of a known fault (refer to California Geological Survey Special Publication 42)

ii. Strong seismic groundshaking

iii. Seismic-related ground failure, including liquefaction

iv. Landslides

L.b Result in substantial soil erosion or the loss of topsoil

L.c Be located on a geologic or soil unit that is unstable, or that would become unstable as a result of the Project, and potentially result in on-site or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse

L.d Be located on expansive soil, as defined in Section 1802.3.2 of the 2007 SFBC, creating substantial risks to life or property

L.e Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater

L.f Change substantially the topography or any unique geologic or physical features of the site

Analytic Method

Preliminary geotechnical assessment of the Project site, including both Candlestick Point and HPS Phase II, has been completed by ENGEO for the Applicant.[409] PBS&J staff have peer-reviewed all ENGEO reports. The preliminary geotechnical assessment was based on previous site-specific geotechnical and hazardous material investigations, some of which include subsurface borings, and review of published geologic reports and maps. The preliminary geotechnical assessment report provides a summary and compilation of available geotechnical information that has been used as part of the analysis of geologic, seismic, and geotechnical issues for this EIR.

This preliminary geotechnical assessment is the first step in identifying, evaluating, and addressing the geotechnical conditions on the Project site and provides necessary information and recommendations to support Project planning and conceptual-level design. Site-specific, design-level geotechnical studies would be completed on a parcel-by-parcel basis during development of construction plans for Project infrastructure and buildings.[410] During the final design, development of individual blocks and foundation recommendations, which may involve further geotechnical exploration, would be required. For high-rise structures, a unique foundation recommendation report would be required for each building.

The Project would develop residential uses, commercial space, office and research and development space, civic and community uses, open space, a marina, and a new 49ers Stadium. Project structures would be designed in accordance with the current SFBC, and would be based on design criteria resulting from required evaluation of site-specific geologic and seismic hazards, including potential for fault rupture, ground motions generated by earthquakes (groundshaking), slope instability, liquefaction, lateral spreading, settlement, and loss of soil strength. In addition to evaluating potential long-term or operational impacts from seismic hazards, potentially corrosive soils, or expansive soils, this section also analyzes short-term soils impacts that could occur during construction, such as erosion and local slope instability. With regard

[409] ENGEO, Inc., *Preliminary Geotechnical Conceptual Design Report Hunters Point Shipyard Phase II and Candlestick Point, San Francisco, California*, May, 2009.
[410] ENGEO, 2009.

to the marina component of the Project, the analysis in this section considers the landside improvements (which could include parking, restroom facilities, a classroom to teach sailing, and a harbormaster's office) that could be affected by geologic hazards, and shoreline modifications that would be needed to accommodate the gangways and extension of utility infrastructure.

The analysis includes review of regional and local geologic maps and reports, as well as Project-specific geologic and geotechnical reports to identify geologic conditions and geologic hazards in the Project site that, because of their proximity, could be directly or indirectly affected by the Project or affect the Project itself. The overall geotechnical and soil conditions across the Project site are similar. To determine potential effects of the Project that relate to geologic hazards during construction and operation, this section analyzes the Project site with respect to identified geological hazards, such as landslides, unstable slopes, liquefaction hazards, and active faults.

Table III.L-4 (Summary of Geologic Conditions, Design Details, and Treatments) through Table III.L-8 (Geotechnical Treatment for HPS Phase II Geotechnical Subparcels) summarize the geological and geotechnical information compiled by ENGEO for the portions of the Project site proposed for construction of physical facilities related to the uses listed above. Table III.L-4 summarizes the geological conditions, design details, and treatments available for the Project site. Table III.L-5 (Grading and Fill Conditions for Candlestick Point Geotechnical Subparcels) and Table III.L-6 (Grading and Fill Conditions for HPS Phase II Geotechnical Subparcels) provide the grading and fill conditions for the geotechnical subparcels. Table III.L-7 (Geotechnical Treatments for Candlestick Point Subparcels) and Table III.L-8 (Geotechnical Treatments for HPS Phase II Subparcels) provide the geotechnical treatments and foundation types for structures in each geotechnical subparcel. Figure III.L-4 (Geotechnical Subparcels) shows the location and boundaries of the geotechnical subparcels and illustrates the relationship of the Project's districts to the geotechnical subparcels identified in Table III.L-5 and Table III.L-6.

Table III.L-4 Summary of Geologic Conditions, Design Details, and Treatments

Districts	*Candlestick Point*	*HPS Phase II*
Geologic Conditions	Artificial Fill thickness up to 70 ft; Bay Mud thickness up to 70 ft; Bedrock elevations range from -220 to + 150 ft (SFCD; Groundwater elevations range from -3 to -9 ft (SFCD)	Artificial Fill thickness up to 50 ft; Bay Mud thickness up to 40 ft; Bedrock elevations range from -200 to +50 ft (SFCD); Groundwater elevations range from -1 to -15 ft (SFCD)
Design Details	Low-rise residential, mid- and high-rise towers with below grade parking, low- and mid-rise commercial; bridge and roadway corridor	Low-rise and mid-rise residential, low- to mid-rise mixed-use, and commercial; high-rise towers; sports facility and parking, utility corridor
Treatments	Mat, spread footing and deep foundations; foundation selection on pad-by-pad basis; depth of foundations determined during design level study; some remedial grading and placement of geogrid; some surcharging; and some overexcavation for utilities	Mat and deep foundations; foundation selection on pad-by-pad basis; depth of foundations determined during design level study; some remedial grading; and some overexcavation for utilities

Table III.L-7 Geotechnical Treatments for Candlestick Point Geotechnical Subparcels

Subareas	*Geotech Subparcel*	*Development Type*	*Proposed Geotechnical Remediation*	*Proposed Foundations*
Candlestick Point North	H	Low-rise residential structures with basement parking level (10 ft deep). Mid-rise and high-rise towers on podium with basement (10 ft deep).	Remove and recompact undocumented fill within 5 feet of finish grade. Placement of geogrid below shallow foundations. Possible surcharging in select areas.	Low-rise structures supported on structural mat. Mid-rise structures will vary from shallow to deep foundations to be determined on a pad-by-pad basis. High-rise structures on deep foundations.
Alice Griffith	G1	Low-rise residential structures constructed at grade.	Remove and recompact undocumented fill within 5 feet of finish grade. Placement of geogrid below shallow foundations.	Low-rise structures supported on structural mat.
	G2	Low-rise residential structures constructed at grade.	Remove and recompact undocumented fill within 5 feet of finish grade.	Low-rise structures supported on shallow foundation on bedrock or shallow engineered fill.
Jamestown Ave.	J	Mid-rise residential structures constructed at grade.	Remove and recompact undocumented fill within 5 feet of finish grade.	Mid-rise structures supported on shallow foundation on bedrock or shallow engineered fill.
Candlestick Point Center	K1	Mid-rise commercial structures constructed at grade.	Remove and recompact undocumented fill within 5 feet of finish grade.	Mid-rise structures supported on shallow foundation on bedrock or shallow engineered fill.
	K2	Mid-rise commercial structures constructed at grade.	Remove and recompact undocumented fill within 5 feet of finish grade.	Mid-rise structures will vary from shallow to deep foundations to be determined on a pad-by-pad basis.
Candlestick Point South	L1	Low-rise residential with ½ basement (5 ft deep) parking level. One high-rise building located mid-parcel along western boundary.	Remove and recompact undocumented fill within 5 feet of finish grade. Placement of geogrid below shallow foundations. Surcharging over entire parcel.	Low-rise structures supported on structural mat. High-rise structures supported on deep foundations.
	L2	Mid-rise mixed-use structures constructed at grade.	Remove and recompact undocumented fill within 5 feet of finish grade.	Mid-rise structures supported on deep foundations.
Yosemite Slough Bridge	YB	Bridge and roadway corridor	Remove and recompact undocumented fill within 5 feet of finish grade. Placement of geogrid below roadway and approach.	Bridge structure supported on deep foundations.

Table III.L-8 Geotechnical Treatment for HPS Phase II Geotechnical Subparcels

Subareas	*Geotech Subparcel*	*Development Type*	*Proposed Geotechnical Remediation*	*Proposed Foundations*
Hunters Point and Hunters Point Village Center (Parcel B)	B1 (Includes Hunters Point Village Center)	Low-rise and mid-rise residential and mid-rise mix-use structures constructed at grade	Remove and recompact undocumented fill within 5 feet of finish grade. Placement of geogrid below shallow foundations.	Low-rise structures supported on structural mat. Mid-rise structures supported on deep foundations.
	B2	Low-rise residential with one high-rise building at the east corner constructed at grade	Remove and recompact undocumented fill within 5 feet of finish grade.	Structures supported on deep foundations founded in competent material.
	B3	Park/open space and surface water treatment facilities constructed at grade	No remedial measures planned.	No structures proposed.
Research and Development (Parcel C)	C1	Mid-rise commercial structures constructed at grade	Remove and recompact undocumented fill within 5 feet of finish grade. Placement of geogrid below shallow foundations.	Low-rise structures supported on structural mat. Mid-rise structures will vary from shallow to deep foundations to be determined on a pad-by-pad basis.
	C2	Mid-rise commercial structures constructed at grade	Remove and recompact undocumented fill within 5 feet of finish grade.	Structures supported on deep foundations founded in competent material.
Stadium (Parcel D and E)	Stadium	Professional level sport facility with playing field	Remove and recompact undocumented fill within 5 feet of finish grade.	Structures supported on deep foundations founded in competent material.
	Parking	Turf area for stadium parking capable of supporting recreation	Gravity utilities designed for on-going settlement.	No structures proposed.
Roadways	UC1	Utility corridor	No remedial measures planned.	No structures proposed.
	UC2	Utility corridor and traffic thoroughfare	No remedial measures planned.	No structures proposed.
	UC3	Utility corridor and traffic thoroughfare	No remedial measures planned.	No structures proposed.

Table III.L-9 (Summary of Waterfront Structures Field Investigative Observations) summarizes the condition of the existing structures along the area that would become waterfront open space with implementation of the Project. Table III.L-10 (Overview of Waterfront Structures Construction Activities) indicates the work proposed (demolition, repair, fill, and/or construction) to turn the shoreline areas into stable open space. Marina facilities including a floating dock system with guide piles and vessel berths, concrete sheet pile breakwaters supported by batter piles, steel dolphin piles with floating donut-type fenders, and landside marina-serving facilities and utilities (dock abutment, parking lot, restrooms, sewage pump-out, harbormaster office) would be constructed in the open space. Shoreline stabilization treatments would include grading and filling to raise the ground surface, rock slopes and buttresses for protection for portions of the shoreline, and timber cribs to support the remaining piers and wharves. Figure III.L-4

GEOTECHNICAL SUBPARCELS

FIGURE III.L-4

shows the shoreline areas outside the geotechnical subparcels (but within the Project boundaries) that would become open space.

Table III.L-9 Summary of Waterfront Structures Field Investigative Observations

Facility	*Condition Rating*	*General Comments*
Wharf at Berth 55 to 61 (Parcel B)	Fair	Concrete structural elements appear to be sound. Minor spalling
Drydocks 2 and 3 (Parcel C)	Poor	Vertical cracks extending full height of walls, air pockets have expanded into large voids.
Berths 1 and 2 (Parcel C)	Serious	Advanced deterioration, deck edge spalling, exposed rebar, pile cracking, apparent collision/impact damage, broken concrete support elbows.
Berth 3 and 4 (Parcel C)	Poor	Advanced deterioration, frequent spalls and corrosion cracks, some exposed corroded rebar.
	Poor to Serious Sta. 10+60 to south edge of pile supported Berth 2 (U/W)	Advanced deterioration, open corrosion spalls with exposed rebar, spalls 6 inches deep.
Berth 5 (Parcel C)	Poor	Advanced open corrosion spalling, impact spalls, cracks and delaminations spalls up to approx. 100 sq. ft.
Berths 6 and 7 (Parcel C)	Poor	Advanced deterioration, open corrosion spalling, cracking on 20% or more walls, 1 to 10 sq. ft. spalls.
Berths 8 and 9	Poor	Advanced corrosion spalling, cracking, and delamination of 20% or more for walls, vertical spalls along cold joints.
Drydock 4 (Parcel C)	Poor	Advanced deterioration, more than 40% has patches of open and closed corrosion spalls and consistent delaminations (full height).
Berth 10 (Parcel D)	Poor	Open corrosion spalls and cracks along 20% or more of the wall. Exposed rebar along damages below caping.
Berth 11 (Parcel D)	Serious	Advanced deterioration and broken concrete throughout majority of wall. Open corrosion spalls and cracks.
Berths 12 and 13 (Parcel D)	Poor	Advanced deterioration along 25% or more; open corrosion spalls and delamination patches; exposed rebar, corrosion cracks along walls.
Berth 14 (Parcel D)	Poor	More than 30% of concrete wall has damages; spalls, exposed and corroded rebar; patches of delaminations and open corrosion spalls at the caping. Spalling at vertical cold joints.
Berths 15–22 and 29 (Parcel D)	Serious	Top 2 ft has 50% to 100% section loss; gaps found between steel sheets. Majority of concrete cap is spalled and exposed rebar. Damage at Berth 29 suspected to be caused by impact.

Construction Impacts

Impact GE-1: Soil Erosion

Impact of Candlestick Point

Impact GE-1a **Construction at Candlestick Point, including the Yosemite Slough bridge, would not result in the loss of topsoil caused by soil erosion. (Less than Significant with Mitigation) *[Criterion L.b]***

Construction activities in the Candlestick Point site, such as removal of paved areas, grading, and excavation, could remove stabilizing vegetation and expose areas of loose soil that, if not properly stabilized, could be subject to soil loss and erosion by wind and stormwater runoff. Newly constructed and compacted engineered slopes could undergo substantial erosion through dispersed sheet flow runoff, and more concentrated runoff can result in the formation of erosional channels and larger gullies, each compromising the integrity of the slope and resulting in significant soil loss. The erosion hazard rating for the local soils in the Candlestick Point site is slight to severe.

Requirements to control surface soil erosion during and after construction at Candlestick Point would be implemented with mitigation measure MM HY-1a.1. The requirements of this mitigation measure are described under Impact HY-1a in Section III.M (Hydrology and Water Quality) and include implementation of a Stormwater Pollution Prevention Plan (SWPPP) and use of best management practices (BMPs) for construction sites. Mitigation measure MM HY-1a.1 would require preparation of a SWPPP and would be required to identify the specific measures and BMPs that are applicable to Candlestick Point construction activities. Installation of erosion mitigation measures would be the responsibility of the Project contractor and would be monitored by DBI inspectors for compliance with the SFBC requirements. Adherence to these requirements through the implementation of standard BMPs for the control of erosion during construction would include a variety of techniques that would be implemented based on site-specific conditions and could include plastic covers and erosion control blankets, soil binders, silt fencing, straw bales, wood mulch, and drainage ditches. Erosion controls could include performing construction activities in the dry season, and minimizing removal of, and damage to native vegetation. To control an increase in dust during construction activities, disturbed areas could be sprayed with water, or a non-toxic soil stabilizer. (Also refer to Section III.H (Air Quality) regarding construction dust control measures.)

Construction activities for the Yosemite Slough bridge, such as grading and excavation of the bridge approaches, could remove stabilizing vegetation and expose areas of loose soil that, if not properly stabilized, could be subject to soil loss and erosion by wind and stormwater runoff. Newly constructed and compacted engineered slopes could undergo substantial erosion through dispersed sheet flow runoff, and more concentrated runoff can result in the formation of erosional channels and larger gullies, each compromising the integrity of the slope and resulting in significant soil loss. The erosion hazard rating for the local soils in the Candlestick Point site is slight to severe.

With implementation of mitigation measure MM HY-1a.1, adverse effects on the soil, such as soil loss from wind erosion and stormwater runoff, would be avoided or reduced to less-than-significant levels.

Impact of Hunters Point Shipyard Phase II

Impact GE-1b **Construction at HPS Phase II would not result in the loss of topsoil caused by soil erosion. (Less than Significant with Mitigation) *[Criterion L.b]***

The potential for exposure to adverse effects caused by soil erosion in the HPS Phase II site exists. Construction activities, such as grading and excavation, could remove stabilizing vegetation and expose areas of loose soil that, if not properly stabilized, could be subject to soil loss and erosion by wind and stormwater runoff. Newly constructed and compacted engineered slopes could undergo substantial erosion through dispersed sheet flow runoff, and more concentrated runoff can result in the formation of erosional channels and larger gullies, each compromising the integrity of the slope and resulting in significant soil loss. The erosion hazard rating for the local soils in the HPS Phase II site is slight to severe.

Requirements to control surface soil erosion during and after construction at HPS Phase II would be implemented through the requirements of mitigation measure MM HY-1a.1 and adverse effects on the soil, such as soil loss from wind erosion and stormwater runoff, would be avoided or reduced to less-than-significant levels.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-1 **Construction activities associated with the Project would not result in the loss of topsoil caused by soil erosion. (Less than Significant with Mitigation) *[Criterion L.b]***

Construction activities, such as removal of paved areas, grading, and excavation, could remove stabilizing vegetation and expose areas of loose soil that, if not properly stabilized, could be subject to soil loss and erosion by wind and stormwater runoff. Newly constructed and compacted engineered slopes could undergo substantial erosion through dispersed sheet flow runoff, and more concentrated runoff can result in the formation of erosional channels and larger gullies, each compromising the integrity of the slope and resulting in significant soil loss. Requirements to control surface soil erosion during and after construction associated with the Project would be implemented through the requirements of mitigation measure MM HY-1a.1 and adverse effects on the soil such as soil loss from wind erosion and stormwater runoff would be avoided or reduced to a less-than-significant level.

Impact GE-2: Settlement from Dewatering Activities

Impact of Candlestick Point

Impact GE-2a **Construction at Candlestick Point and the Yosemite Slough bridge would not result in damage to structures from settlement caused by lowering of groundwater levels. (Less than Significant with Mitigation) *[Criterion L.c]***

At Candlestick Point, construction activities would have the potential to affect groundwater levels. Project construction may include dewatering procedures during excavation, construction, and operation of foundations and buried utilities. Groundwater levels in the artificial fill and the underlying estuarine deposits at Candlestick Point generally are less than 15 feet below the ground surface and experience varying degrees of tidal fluctuation. Some minor dewatering may be needed to reduce heads to several feet or more below excavation bottoms and to address seepage and the potential for settlement. Dewatering during construction activities could cause settlement of adjacent soils; however, since there are no existing structures at Candlestick Point that will remain with the Project, no damage to overlying foundations of existing buildings would result.

Construction activities for the Yosemite Slough bridge would have the potential to affect groundwater levels. Project construction may include dewatering procedures during excavation, construction, and operation of foundations and buried utilities. Groundwater levels in the artificial fill and the underlying estuarine deposits near Yosemite Slough are generally less than 15 feet below the ground surface and experience varying degrees of tidal fluctuation. Some minor dewatering may be needed to reduce heads to several feet or more below excavation bottoms and to address seepage and the potential for settlement. However, as there are no structures adjacent to the location of the proposed bridge, dewatering during construction would not affect foundations of existing structures.

Section 1803.1 of the SFBC requires that excavations for any purpose not remove support from adjacent or nearby structures without first protecting them against settlement or lateral movement. To ensure this protection during dewatering, the following mitigation measure shall be implemented where adjacent or nearby structures exist:

MM GE-2a *Mitigation to Minimize Dewatering Impacts During Construction. Prior to the issuance of any permit for a construction activity that would involve dewatering that could affect structures on adjacent or nearby properties, the Applicant shall, in compliance with Section 1803.1 of the* San Francisco Building Code *(SFBC), include in the permit application methods and techniques to ensure that dewatering would not lower the water table such that unacceptable settlement (as determined by a California Certified Engineering Geologist [CEG] or California Registered Geotechnical Engineer [GE]) at adjacent or nearby properties would occur. Such methods and technologies shall be based on the specific conditions at the construction site and could include, but are not necessarily limited to, the following:*

- *Excavating below the groundwater table in confined areas with steel sheet piling driven below the base elevation of the proposed excavation, installation of bracing to support the excavation walls as required and, if necessary, underpinning the foundations of adjacent structures. Subsequently, the excavation would be carried out and seepage that enters the dammed area would be pumped out.*
- *Perform dewatering using methods such as wellpoint systems, drainage ditches, and sump pumps.*

The excavation or dewatering methods shall be monitored to detect ground settlement and to monitor individual dewatering activities in the vicinity of an excavation. Monitoring results shall be submitted to the San Francisco Department of Building Inspection (DBI). In the event of unacceptable ground movement, as determined by DBI inspections and/or the review of monitoring results, all excavation work shall cease and corrective measures (including, for example, different dewatering methods and/or ground stabilization methods) shall be determined by the Project CEG or GE and reviewed and approved by DBI. No construction permit involving dewatering would be issued until the Project CEG or GE and DBI have approved dewatering and/or ground stabilization methods. The Project CEG or GE shall implement the corrective measures and continue monitoring activities.

With implementation of those dewatering techniques, groundwater level monitoring, and subsurface controls, as specified in the SFBC and required by mitigation measure MM GE-2a, groundwater levels in the area would not be lowered such that that unacceptable settlement at adjacent or nearby properties would occur. Consequently, settlement hazards related to dewatering would be less than significant.

Impact of Hunters Point Shipyard Phase II

Impact GE-2b **Construction at HPS Phase II would not result in damage to structures caused by settlement from lowering of groundwater levels. (Less than Significant with Mitigation) *[Criterion L.c]***

At HPS Phase II, construction activities would have the potential to affect groundwater levels. Project construction may include dewatering procedures during excavation, construction, and operation of foundations and buried utilities. The dewatering could cause settlement of adjacent soils that could damage the overlying foundations of existing buildings. Groundwater levels in the artificial fill and the underlying estuarine deposits at HPS Phase II are generally less than 15 feet below the ground surface and experience varying degrees of tidal fluctuation. Some minor dewatering may be needed to reduce heads to several feet or more below excavation bottoms and to address seepage and the potential for settlement.

The requirements of Section 1803.1 of the SFBC as indicated above would be applicable to dewatering activities at HPS Phase II. With implementation of the dewatering techniques, groundwater level monitoring, and subsurface controls as specified in the SFBC and required by mitigation measure MM GE-2a, groundwater levels in the area would not be lowered such that that unacceptable settlement at adjacent or nearby properties would occur. Consequently, settlement hazards related to dewatering would be less than significant.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-2 **Construction activities associated with the Project would not result in damage to structures caused by settlement from lowering of groundwater levels. (Less than Significant with Mitigation) *[Criterion L.c]***

Project construction activities would have the potential to affect groundwater levels. Project construction may include dewatering procedures during excavation, construction, and operation of foundations and buried utilities. The dewatering could cause settlement of adjacent soils that could damage the overlying foundations of existing buildings. Groundwater levels in the artificial fill and the underlying estuarine deposits generally are less than 15 feet below the ground surface and experience varying degrees of tidal fluctuation. Some minor dewatering may be needed to reduce heads to several feet or more below

excavation bottoms and to address seepage and the potential for settlement. With implementation of the dewatering techniques, groundwater level monitoring, and subsurface controls as specified in the SFBC and required by mitigation measure MM GE-2a, groundwater levels in the area would not be lowered such that that unacceptable settlement at adjacent or nearby properties would occur. Consequently, settlement hazards related to dewatering would be less than significant.

Impact GE-3: Destabilization of Bedrock from Rock Removal Activities

Impact GE-3 **Rock removal activities at the Alice Griffith Public Housing site and the Jamestown area would not result in damage to structures from vibration and/or settlement caused by the fracturing of bedrock for excavation. (Less than Significant with Mitigation) *[Criterion L.c]***

At the Alice Griffith Public Housing site and the Jamestown area, the removal of bedrock through heavy equipment methods or controlled rock fragmentation activities would have the potential to fracture rock adjacent to the excavation, thereby destabilizing it and possibly causing settlement of structures above it. Heavy equipment rock removal methods could include ripping (such as a large tractor equipped with a ripper attachment) or mechanical rock-breaking using hammers, hoe-rams, splitters, and/or cutters. Harder areas of bedrock may need to be removed using a technique known as controlled rock fragmentation. Controlled rock fragmentation technologies include pulse plasma rock fragmentation (PPRF), controlled foam injection, and controlled blasting. It may be necessary to use a combination of these techniques. Controlled blasting usually can be performed at noise levels below typical building demolition noise levels (80-100 dBA).[411] PPRF can be performed at noise and vibration levels below those of controlled blasting (1/36 and 1/20, respectively, at 20 meters [about 65 feet]).[412] Controlled foam injection reduces the airblast, flyrock, and fumes associated with uncovered explosive-based techniques.[413]

Controlled blasting fractures bedrock by using explosives to produce a vibration or shockwave that breaks the rock. Controlled foam injection forces an aqueous polymer into existing rock fractures and enlarges them until the rock fails. PPRF uses an electrical impulse to create a flash of extremely high heat that shatters the rock by causing it to expand beyond its capacity to maintain its structural integrity.

The majority of the area at the Alice Griffith Public Housing site consists of thin fill over bedrock and artificial fill underlain by young bay mud over bedrock. The bedrock is at elevations ranging from +45 feet San Francisco City Datum (SFCD) to -10 feet SFCD. The bedrock, which may include localized well-cemented beds, would need to be removed in the northern portion of the parcel to depths ranging from 2 feet to 23 feet below the existing ground surface. It's estimated that 140,000 cubic yards of rock will need to be removed; at least 70 percent of this rock would be removed by heavy equipment, but the remaining 30 percent (approximately 42,000 cubic yards) may need to be removed by controlled rock fragmentation.[414]

414 MACTEC, June, 2009.

The majority of the area at Jamestown is underlain by bedrock at an elevation of +100 feet SFCD to the northeast and +150 feet SFCD to the southwest. Development of this parcel would involve the removal of bedrock, which may include localized well-cemented beds, to depths ranging from 2 feet to 62 feet below the existing ground surface. It's estimated that 140,000 CYs of rock will need to be removed; at least 30 percent of this rock would be removed by heavy equipment; the remaining 70 percent (approximately 98,000 cubic yards) may need to be removed by controlled rock fragmentation. Access constraints caused by the steep slopes in the area may reduce the amount of rock that could be removed using heavy equipment.[415]

Section 1803.1 of the SFBC requires that excavations for any purpose not remove support from adjacent or nearby structures without first protecting them against settlement or lateral movement. To ensure this protection during controlled rock fragmentation activities, the following mitigation measure would be implemented:

MM GE-3 *Mitigation to Minimize Rock Fragmentation Impacts During Construction. Prior to the issuance of any permit for a construction activity that would involve controlled rock fragmentation that could cause settlement or lateral movement of structures on adjacent or nearby properties, the Applicant shall, in compliance with Section 1803.1 of the* San Francisco Building Code *(SFBC), include in the permit application methods and techniques to ensure that controlled rock fragmentation would not cause unacceptable vibration and/or settlement or lateral movement of structures at adjacent or nearby properties. Such methods and technologies shall be based on the specific conditions at the construction site such as, but not limited to, the following:*

- *Pre-excavation surveying of potentially affected structures.*
- *Underpinning of foundations of potentially affected structures, as necessary.*
- *The excavation plan shall include a monitoring program to detect ground settlement or lateral movement of structures in the vicinity of an excavation. Monitoring results shall be submitted to DBI. In the event of unacceptable ground movement, as determined by DBI inspections, all excavation work shall cease and corrective measures shall be implemented. The controlled rock fragmentation program and ground stabilization measures shall be reevaluated and approved by the DBI.*

With implementation of those techniques, ground surface and building damage monitoring, as specified in the SFBC and required by mitigation measure MM GE-3, vibration from controlled rock fragmentation in the area would not cause unacceptable settlement or damage at adjacent or nearby properties would occur. Consequently, settlement hazards related to controlled rock fragmentation would be less than significant. Rock removal activities would not be required at any other areas on the Project site.

[415] MACTEC, June, 2009.

Operational Impacts

Impact GE-4: Seismically Induced Groundshaking

Impact of Candlestick Point

Impact GE-4a **Implementation of the Project at Candlestick Point, including the Yosemite Slough bridge and Alice Griffith Housing, would not expose people or structures to substantial adverse effects caused by seismically induced groundshaking. (Less than Significant with Mitigation) *[Criterion L.a(ii)]***

Candlestick Point

Candlestick Point could be exposed to groundshaking hazards. Groundshaking is the most widespread effect of earthquakes and would pose a seismic threat to the development at Candlestick Point. Active faults capable of producing strong groundshaking exist near the Project site. Most notable of these faults are the San Andreas, San Gregorio, and Hayward Faults. The proposed new structures could experience strong groundshaking from an earthquake on any of these faults.

To address groundshaking, the design-level geotechnical investigations to be performed must include site-specific seismic analyses to evaluate the peak ground accelerations for design of Project components, as required by Chapter 16, Structural Design, and Chapter 18, Soils and Foundations, of the SFBC. Accordingly, the following mitigation measure shall be implemented:

MM GE-4a.1 *Site-Specific Geotechnical Investigation with Seismic Analyses. Prior to the issuance of any building permits for the Project site:*

- *The Applicant shall submit to the San Francisco Department of Building Inspection (DBI) for review and approval a site-specific, design-level geotechnical investigation prepared by a California Certified Engineering Geologist (CEG) or California Registered Geotechnical Engineer (GE), as well as project plans prepared in compliance with the requirements of the* San Francisco Building Code *(SFBC), the* Seismic Hazards Mapping Act*, and requirements contained in CGS Special Publication 117A "Guidelines for Evaluating and Mitigating Seismic Hazards in California." In addition, all engineering practices and analyses of peak ground accelerations and structural design shall be consistent with SFBC standards to ensure that structures can withstand expected ground accelerations. The CEG or GE shall determine and DBI shall approve design requirements for foundations and all other improvements associated with the permit application.*
- *DBI shall employ a third-party CEG and California Registered Professional Engineer (Civil) (PE) to form a Geotechnical Peer Review Committee (GPRC), consisting of DBI and these third-party reviewers. The GPRC shall review the site-specific geotechnical investigations and the site-specific structural, foundation, infrastructure, and other relevant plans to ensure that these plans incorporate all necessary geotechnical mitigation measures. No permits shall be issued by DBI until the GPRC has approved the geotechnical investigation and the Project plans, including the factual determinations and the proposed engineering designs and construction methods.*
- *All Project structural designs shall incorporate and conform to the requirements in the site-specific geotechnical investigations.*
- *The Project CEG or GE shall be responsible for ensuring compliance with these requirements.*

Implementation of site-specific design measures would ensure that Project structures would withstand expected seismic ground accelerations. Consequently, seismic hazards related to groundshaking would be less than significant.

Alice Griffith Public Housing

The Alice Griffith Public Housing site and new development on the site would be subject to HUD approval and Executive Order 12699. The new development would also be subject to the SFBC, which would meet the requirements of the Executive Order. The San Francisco Department of Building Inspection (DBI) would be the agency responsible for implementing and enforcing appropriate seismic design and construction standards for the new development. DBI would be the City's responsible agency. Federal implementation and enforcement of the seismic safety program would be achieved through notification by the City to the building owner, architect, engineer, or contractor of the required minimum standards and requiring written acknowledgement of awareness of the requirements and of intent to comply.

HUD could require some form of compliance certification, such as the engineer's and architect's signed and stamped verification of seismic design codes, standards, and practices used in the design and construction of the buildings, or submittal of Planning Department and/or DBI permit review and inspection documents to HUD. To ensure compliance with any such requirements, the following mitigation measure shall be implemented for the Alice Griffith Public Housing development:

MM GE-4a.2 *Seismic Design Compliance Documentation. Prior to the issuance of building permits for the replacement of the Alice Griffith Public Housing site, the Applicant shall submit any and all seismic design compliance documentation to the HUD, as required by that agency. The Project Developer shall confirm, by copy of all documents submitted, including transmittal, compliance with this requirement to DBI. The Project California Certified Engineering Geologist (CEG) or California Registered Geotechnical Engineer (GE) shall be responsible for verifying Project compliance with this requirement.*

Implementation of mitigation measures MM GE-4a.1 and MM GE-4a.2 would ensure that impacts to the Alice Griffith Public Housing from seismic ground acceleration and groundshaking would be reduced a less-than-significant level.

Yosemite Slough Bridge

The Yosemite Slough bridge could be exposed to groundshaking hazards. Groundshaking is the most widespread effect of earthquakes and would pose a seismic threat to the Project. Active faults capable of producing strong groundshaking exist near the Project site. Most notable of these faults are the San Andreas, San Gregorio, and Hayward Faults. The proposed new structures could experience strong groundshaking from an earthquake on any of these faults.

To address groundshaking, design-level geotechnical investigations as required by mitigation measure MM GE-4a.3 would include site-specific seismic analyses to evaluate the seismic safety of bridge design of the bridge based on Caltrans and Department of Public Works Bureau of Engineering (BOE specifications. The following mitigation measure shall be implemented:

MM GE-4a.3 *Site-specific Seismic Analyses to Ensure Safety of Bridge Design. Prior to the issuance of any building permits for the Project site, the California Certified Engineering Geologist (CEG) or California Registered Geotechnical Engineer (GE) for the Project shall confirm that the design-level geotechnical*

*investigation for the Yosemite Slough bridge is based on Caltrans specifications (*Bridge Design Specifications*, Section 20 of* Bridge Memos to Designers*,* Seismic Design Criteria *as previously described) and meets the San Francisco Department of Public Works Bureau of Engineering (BOE) requirements. The Project CEG or GE and California Registered Structural Engineer ((SE) shall approve bridge design. No building permits shall be issued until the CEG or GE and SE verify that the Project's bridge design complies with all Caltrans specifications and BOE requirements.*

Implementation of mitigation measures MM GE-4a.1 and MM GE-4a.3 would be required for the bridge. Based on the seismic analyses required by mitigation measures MM GE-4a.1 and MM GE-4a.3, bridge design would be modified or strengthened and constructed to the highest feasible seismic safety standards consistent with the BOE requirements, as deemed appropriate by the Project CEG or GE and SE and verified by BOE, if the anticipated seismic forces (calculated peak vertical and horizontal ground accelerations caused by groundshaking) were found to be greater than anticipated. Compliance with these BOE requirements would ensure potential impacts on the bridge from groundshaking would be less than significant.

Impact of Hunters Point Shipyard Phase II

Impact GE-4b **Implementation of the Project at HPS Phase II would not expose people and structures to substantial adverse effects caused by seismically induced groundshaking. (Less than Significant with Mitigation) *[Criterion L.a(ii)]***

There is a potential for exposure to adverse effects caused by groundshaking in the HPS Phase II site. Groundshaking is the most widespread effect of earthquakes and would pose a seismic threat to the development at HPS Phase II. Active faults capable of producing strong groundshaking exist near the Project site. Most notable of these faults are the San Andreas, San Gregorio, and Hayward Faults. The proposed new structures could experience strong groundshaking from an earthquake on any of these faults.

To address groundshaking, the design-level geotechnical investigations to be performed must include site-specific seismic analyses to evaluate the peak ground accelerations for design of Project components, as required by Chapter 16 (Structural Design) and Chapter 18 (Soils and Foundations) of the SFBC. Accordingly, mitigation measure MM GE-4.a1 would be implemented for development of HPS Phase II. Based on the seismic analyses, structure designs would be modified or strengthened and constructed to the highest feasible seismic safety standards, consistent with the requirements of the SFBC, as deemed appropriate by the Project engineer and verified by DBI, if the anticipated seismic forces (calculated peak vertical and horizontal ground accelerations caused by groundshaking) were found to be greater than anticipated. Implementation of this mitigation measure would ensure that potential impacts from groundshaking would be less than significant.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-4 **Implementation of the Project would not expose people and structures to substantial adverse effects caused by seismically induced groundshaking. (Less than Significant with Mitigation) *[Criterion L.a(ii)]***

The potential for exposure to adverse effects caused by seismic groundshaking exists at the Project site. Mitigation measures MM GE-4a.1, MM GE-4a.2, and MM GE-4a.3 would require design-level geotechnical investigations that would include site-specific seismic analyses to evaluate the peak ground accelerations for design of Project structures and the Yosemite Slough bridge, as required by the SFBC

and Caltrans. Implementation of these mitigation measures would ensure that potential impacts from groundshaking would be less than significant.

Impact GE-5: Seismically Induced Ground Failure

Impact of Candlestick Point

Impact GE-5a **Implementation of the Project at Candlestick Point, including the Alice Griffith Housing and Yosemite Slough bridge, would not expose people or structures to substantial adverse effects caused by seismically induced ground failure such as liquefaction, lateral spreading, and settlement. (Less than Significant with Mitigation) *[Criterion L.a(iii)]***

Candlestick Point

The Candlestick Point site could be exposed to liquefaction hazards. Liquefaction-related phenomena can include lateral spreading, ground oscillation, loss of bearing strength, vertical settlement from densification (subsidence), buoyancy effects, sand boils, and flow failures, all of which could cause damage to the proposed structures in the Candlestick Point site. Damage from liquefaction and lateral spreading is generally most severe when liquefaction occurs within 15 to 20 feet below the ground surface. The Orthents and Urban Land soils in the lowland areas of the Candlestick Point site have a very high potential for liquefaction. In particular, loosely compacted granular soil below the ground-water table with uniform grain size and low plasticity are most susceptible to liquefaction. Based on the subsurface data reviewed to date, these types of soil deposits generally are limited to isolated pockets and random layers within the overall soil profile, and, therefore, the unmitigated risk is considered low to moderate and can be treated using standard engineering practices to protect improvements, as outlined previously in Table III.L-7 and Table III.L-8.[416] If more extensive zones susceptible to liquefaction were encountered during future exploration, further mitigation measures could be necessary. The proposed foundations for structures, vaults, and pipelines would be the components most vulnerable to damage from liquefaction-related phenomena. Localized hazards could occur in open space areas, but mitigation would not be necessary where no habitable structures or critical utilities would be present.

Seismically induced settlement can occur in areas underlain by compressible or poorly consolidated sediments. Stream channel deposits and recent valley alluvium generally are the most susceptible to earthquake-induced settlement. Additionally, some artificial fills are susceptible to mobilization and densification, resulting in earthquake-induced subsidence. Artificial fills exist in the lowland areas of Candlestick Point (refer to Figure III.L-1). In addition, historical shoreline maps show that artificial fill placement extends as far as 3,300 feet into the Bay.[417]

CGS Special Publication 117A outlines the protocol for analysis and treatment of liquefaction-related hazards, including estimates of vertical settlement and lateral spreading. Prediction of liquefaction-related settlement is necessarily approximate, and related hazard assessment and development of recommendations for treatment of such hazards must be performed conservatively, as recommended by CGS Special Publication 117A. A similarly conservative approach is recommended by CGS Special

[416] ENGEO, 2009.
[417] ENGEO, 2008.

Publication 117A when estimating the amount of localized differential settlement likely to occur as part of the overall predicted settlement: localized differential settlements up to two-thirds of the total settlements anticipated must be assumed until more precise predictions of differential settlements can be made.

Design and construction of the structures and facilities at Candlestick Point would incorporate appropriate engineering practices to ensure seismic stability, some of which are explained in more detail below, as required by Chapter 16, Structural Design, and Chapter 18, Soils and Foundations, of the SFBC. Sections 1607 through 1614 contain the formulae, tables, and graphs by which the Project engineer would develop the structural specifications for building design and which would be used by DBI to verify the applicability of the specifications. Sections 1804 through 1812 contain similar information for the design and verification of adequate soils and foundation support for individual elements of the Project. Section 1802 requires the use of this information in the seismic analyses prepared for the site-specific investigations that must be prepared in connection with the permits for individual elements of the Project.

Where shallow foundations would be underlain by artificial fill and the estimated settlement would be small, the treatment could employ a combination of removal and recompaction with the placement of geogrid[418] beneath structures to help distribute differential settlement that might occur. Treatment for mid-rise and high-rise structures could include supporting these structures on deep foundations bearing in strata below the potentially liquefiable layer with flexible utility connections to allow some settlement beneath the buildings. Mitigation measure MM GE-4a.1 would reduce risks from liquefaction. If liquefaction estimates were such that MM GE-4a.1 would not address liquefaction and settlement-related impacts adequately, further mitigation would include one or more of the additional structural and/or ground-improvement procedures identified in mitigation measure MM GE-5a. Selection of the appropriate procedures would be dependent on the land use, development type, soil profile, and estimated settlement.

To avoid or reduce the potential liquefaction hazards at Candlestick Point to a less-than-significant level, implementation of mitigation measure MM GE-5a would require the Applicant to comply with site-specific requirements established by State and local codes and by DBI and other agencies that would be involved in reviewing and issuing permits for buildings and infrastructure at the Project site.

To reduce or avoid impacts related to seismically induced ground failure such as liquefaction, lateral spreading, and/or settlement where the measures described above are not adequate, the following mitigation measure shall be implemented.

MM GE-5a *Site-Specific Geotechnical Investigation with Analyses of Liquefaction, Lateral Spreading and/or Settlement. Prior to issuance of building permits for the Project site:*

- *The Applicant shall submit to the San Francisco Department of Building Inspection (DBI) for review and approval a site-specific, design-level geotechnical investigation prepared by a California Certified Engineering Geologist (CEG) or California Registered Geotechnical Engineer (GE), as well as project plans prepared in compliance with the requirements of the San Francisco Building Code (SFBC), the Seismic Hazards Mapping Act, and requirements contained in CGS Special Publication 117A "Guidelines for Evaluating and Mitigating Seismic Hazards in California."*

[418] Geogrids are synthetic fabrics (fiberglass, polyester, treated steel, etc.) formed into nets with openings more than ¼ inch in size to allow the fabric to interlock with surrounding soil, rock, and other below-ground-level materials and to function as reinforcement.

In addition, all engineering practices, and analyses of structural design shall be consistent with SFBC standards to ensure seismic stability, including reduction of potential liquefaction hazards.

- *DBI shall employ a third-party CEG and California Registered Professional Engineer (Civil) (PE) to form a Geotechnical Peer Review Committee (GPRC), consisting of DBI and these third-party reviewers. The GPRC shall review the site-specific geotechnical investigations and the site-specific structural, foundation, infrastructure, and other relevant plans to ensure that these plans incorporate all necessary geotechnical mitigation measures. No permits shall be issued by DBI until the GPRC has approved the geotechnical investigation and the Project plans, including the factual determinations and the proposed engineering designs and construction methods.*
- *All Project structural designs shall incorporate and conform to the requirements in the site-specific geotechnical investigations.*
- *The site-specific Project plans shall incorporate the mitigation measures contained in the approved site-specific geotechnical reports to reduce liquefaction hazards. The engineering design techniques to reduce liquefaction hazards shall include proven methods generally accepted by California Certified Engineering Geologists, subject to DBI and GPRC review and approval, including, but not necessarily limited to:*

Structural Measures

- *Construction of deep foundations, which transfer loads to competent strata beneath the zone susceptible to liquefaction, for critical utilities and shallow foundations*
- *Structural mat foundations to distribute concentrated load to prevent damage to structures*

Ground Improvement Measures

- *Additional over-excavation and replacement of unstable soil with engineering-compacted fill*
- *Dynamic compaction, such as Deep Dynamic Compaction (DDC) or Rapid Impact Compaction (RIC), to densify loose soils below the groundwater table*
- *Vibro-compaction, sometimes referred to as vibro-floatation, to densify loose soils below the groundwater table*
- *Stone columns to provide pore pressure dissipation pathways for soil, compact loose soil between columns, and provide additional bearing support beneath foundations*
- *Soil-cement columns to densify loose soils and provide additional bearing support beneath foundations*
- *The Project CEG or GE shall be responsible for ensuring compliance with these requirements.*

Implementation of mitigation measures MM GE-4a.1 and MM GE-5a would reduce or avoid impacts related to seismically induced ground failure such as liquefaction, lateral spreading, and/or settlement by applying structural and ground improvement measures to minimize these risks. Implementation of this mitigation would reduce the impact to less than significant.

Alice Griffith Housing

New development on the Alice Griffith Public Housing site would be subject to HUD approval and Executive Order 12699. The new development would be subject to the SFBC, which would meet the requirements of the Executive Order. The San Francisco Department of Building Inspection (DBI) would be the agency responsible for implementing and enforcing appropriate seismic design and construction standards for the new development. DBI would be the City's responsible agency. Federal implementation

and enforcement of the seismic safety program would be achieved through notification by the City to the building owner, architect, engineer, or contractor of the required minimum standards and requiring written acknowledgement of awareness of the requirements and of intent to comply.

HUD could require some form of compliance certification, such as the engineer's and architect's signed and stamped verification of seismic design codes, standards, and practices used in the design and construction of the buildings, or submittal of Planning Department and/or DBI permit review and inspection documents to HUD. Mitigation measures MM GE-4a.1, MM GE-4a.2, and MM GE-5a would apply to this impact, and would reduce this impact a less-than-significant level.

Yosemite Slough Bridge

The Yosemite Slough bridge area could be exposed to liquefaction hazards, as described in the discussion regarding Candlestick Point, above. Artificial fills occur in the lowland areas near the proposed Yosemite Slough bridge (refer to Figure III.L-1). In addition, historical shoreline maps show that artificial fill placement extends as far as 1,100 feet into the Bay near the proposed Yosemite Slough bridge.[419]

CGS Special Publication 117A outlines the protocol for analysis and treatment of liquefaction-related hazards, including estimates of vertical settlement and lateral spreading. Design and construction of the bridge structures would incorporate appropriate engineering practices and building codes to ensure seismic stability, as required by BOE Standard Specifications Part 4 (Structures). The design of the bridge would be based on Caltrans specifications (*Bridge Design Specifications*, Section 20 of *Bridge Memos to Designers, Seismic Design Criteria*), and would meet the BOE requirements. Compliance with BOE requirements would ensure potential impacts would be reduced to a less-than-significant level. Bridge bents likely would be supported on deep foundations bearing in strata below the potentially liquefiable layer. At the bridge approaches, it could be possible to employ a combination of removal and recompaction using engineered fill with the placement of geogrid beneath structures to help distribute differential settlement that might occur. Mitigation measure MM GE-4a.1 would reduce risks from liquefaction. If liquefaction estimates were such that MM GE-4a.1 would not address liquefaction and settlement-related impacts adequately, further mitigation would include one or more of the additional structural and/or ground-improvement identified in mitigation measures MM GE-5a and MM GE-4a.3. Selection of the appropriate procedures would be dependent on the bridge design, soil profile, and estimated settlement.

To reduce the impact of potential liquefaction hazards to a less-than-significant level at Yosemite Slough bridge, implementation of mitigation measure MM GE-4a.1, MM GE-4a.3, and MM GE-5a would require Applicant to comply with site-specific requirements established by DBI and other agencies that would be involved in reviewing and issuing permits for buildings and infrastructure at the Project site. Design and construction of the bridge structures would incorporate appropriate engineering practices as outlined in the site-specific geotechnical report and in Caltrans requirements to ensure seismic stability, as required by BOE Standard Specifications Part 4 (Structures). Implementation of these mitigation measures would ensure compliance with the requirements of the Building Code, Caltrans, and the BOE, and would avoid or reduce potential impacts from seismically induced ground failure a less-than-significant level.

[419] ENGEO, 2008.

Impact of Hunters Point Shipyard Phase II

Impact GE-5b **Implementation of the Project at HPS Phase II would not expose people or structures to substantial adverse effects caused by seismically induced ground failure such as liquefaction, lateral spreading, and settlement. (Less than Significant with Mitigation) *[Criterion L.a(iii)]***

Structures at the HPS Phase II site could be exposed to seismically induced ground failure, including liquefaction hazards. Liquefaction-related phenomena could include lateral spreading, ground oscillation, loss of bearing strength, vertical settlement from densification (subsidence), buoyancy effects, sand boils, and flow failures, any of which could cause damage to the proposed structures in the HPS Phase II site. Damage from liquefaction and lateral spreading generally is most severe when liquefaction occurs within 15 to 20 feet below the ground surface. The Orthents and Urban Land soils in the lowland areas of the HPS Phase II site have a very high potential for liquefaction. In particular, loosely compacted granular soil with uniform grain size and low plasticity below the groundwater table are most susceptible to liquefaction. Because these types of soil deposits generally are limited to isolated pockets and random layers in the overall soil profile, with the exception of the area in the vicinity of the southeast-facing shoreline in Parcels D and E at HPS, the unmitigated risk is considered low to moderate: it can be treated using standard engineering practices to protect improvements.[420] If more extensive zones susceptible to liquefaction were encountered during future exploration, as may be the case in the vicinity of the southeast-facing shoreline in Parcels D and E at HPS which would become open space, additional mitigation measures, such as those described in MM GE-5a, above, could be necessary. The proposed foundations for structures, vaults, and pipelines would be the components most vulnerable to damage from liquefaction-related phenomena. Localized hazards may occur in open space areas, without mitigation, where habitable structures or critical utilities would not be present.

Seismically induced settlement could occur in areas underlain by compressible or poorly consolidated sediments. Stream channel deposits and recent valley alluvium generally are the most susceptible to earthquake-induced settlement. Additionally, some artificial fills are susceptible to mobilization and densification, resulting in earthquake-induced subsidence. Artificial fills exist in the lowland areas of HPS Phase II (refer to Figure III.L-1). In addition, historical shoreline maps show that artificial fill placement extends as far as 3,300 feet into the Bay.[421]

CGS Special Publication 117A outlines the protocol for analysis and treatment of liquefaction-related hazards, including estimates of vertical settlement and lateral spreading. Prediction of liquefaction-related settlement is necessarily approximate, and related hazard assessment and development of recommendations for treatment of such hazards must be performed conservatively, as recommended by CGS Special Publication 117A. A similarly conservative approach is recommended by CGS Special Publication 117A when estimating the amount of localized differential settlement likely to occur as part of the overall predicted settlement: localized differential settlements up to two-thirds of the total settlements anticipated must be assumed until more precise predictions of differential settlements can be made.

[420] ENGEO, 2009.
[421] ENGEO, 2008.

Design and construction of the structures and facilities in the HPS Phase II site would incorporate appropriate engineering practices to ensure seismic stability, some of which are explained in more detail below, as required by Chapter 16 (Structural Design) and Chapter 18 (Soils and Foundations) of the SFBC. Sections 1607 through 1614 contain the formulae, tables, and graphs by which the Project engineer would develop the structural specifications for building design and which would be used by DBI to verify the applicability of the specifications. Sections 1804 through 1812 contain similar information for the design and verification of adequate soils and foundation support for a project. Section 1802 requires the use of this information in the seismic analyses of the Project site.

Where shallow foundations would be underlain by artificial fill and the estimated settlements are small, treatment could employ a combination of removal and recompaction with the placement of geogrid beneath structures to help distribute differential settlement that might occur. Treatment for mid-rise and high-rise structures could include supporting these structures on deep foundations bearing in strata below the potentially liquefiable layer with flexible utility connections to allow some settlement beneath the buildings. Mitigation measure MM GE-4a.1 would reduce risks from liquefaction. If liquefaction estimates were such that MM GE-4a.1 would not address liquefaction and settlement-related impacts adequately, further mitigation would include one or more of the additional structural and/or ground-improvement measures identified in mitigation measure MM GE-5a, above. Selection of the appropriate mitigation would be dependent on the land use, development type, soil profile, and estimated settlement. At HPS Phase II, there could be environmental constraints limiting the potential use of certain mitigation measures because of groundwater and soil contamination.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-5 **Implementation of the Project would not expose people or structures to substantial adverse effects caused by seismically induced ground failure such as liquefaction, lateral spreading, and settlement. (Less than Significant with Mitigation)** ***[Criterion L.a(iii)]***

- The potential for adverse effects caused by seismically induced ground failure such as liquefaction, lateral spreading, and settlement exists at the Project site. Mitigation measures MM GE-4a.1, MM GE-4a.2, MM GE-4a.3, and MM GE-5a would require design-level geotechnical investigations must include site-specific seismic analyses to evaluate the peak ground accelerations for design of Project structures, as required by the SFBC through review by DBI. It is anticipated that DBI would employ a third-party engineering geologist and/or civil engineer to form a GPRC. The GPRC would complete the technical review of proposed site-specific structural designs prior to building permit approval. The structural design review required by MM GE-4a.1, MM GE-4a.2, MM GE4a.3, and MM GE-5a would ensure that all necessary methods and techniques would be incorporated in the design for Project foundations and structures to reduce potential impacts from ground failure or liquefaction to a less-than-significant level.

Impact GE-6: Seismically Induced Landslides

Impact of Candlestick Point

Impact GE-6a **Implementation of the Project at Candlestick Point, including the Alice Griffith Housing, would not expose people or structures to substantial adverse effects caused by seismically induced landslides. (Less than Significant with Mitigation) *[Criterion L.a(iv)]***

Candlestick Point

The Candlestick Point site could be exposed to landslide hazards. Earthquakes have the potential to induce landslides on both steep slopes and relatively level ground, especially in upland areas underlain by weathered bedrock or serpentinite. Potential landslide hazards in the Project site are presented in Figure III.L-3. The figure shows that the major landslide hazard area in at Candlestick Point is an approximate 2,500-foot-wide and 2,500-foot-long section on Bayview Hill around Bayview Park Road, east of Highway 101 and west of the State Park.[422]

Risks from landslides can be reduced by employing proven methods generally accepted by California Certified Engineering Geologists, to reduce these hazards. Treatment could employ a combination of removal and recompaction with the placement of geogrid[423] beneath structures and/or supporting mid- and high-rise structures on deep foundations bearing in strata below the potentially liquefiable layer with flexible utility connections to allow some settlement beneath the buildings. Selection of the appropriate procedures would be dependent on the land use, development type, and soil profile. To address the risk of landslides, the following mitigation measure shall be implemented:

MM GE-6a *Site-Specific Geotechnical Investigation with Landslide Risk Analyses. Prior to issuance of building permits for the Project site:*

- *The Applicant shall submit to the San Francisco Department of Building Inspection (DBI) for review and approval a site-specific, design-level geotechnical investigation prepared by a California Certified Engineering Geologist (CEG) or California Registered Geotechnical Engineer (GE), as well as project plans prepared in compliance with the requirements of the San Francisco Building Code (SFBC), the Seismic Hazards Mapping Act, and requirements contained in CGS Special Publication 117A "Guidelines for Evaluating and Mitigating Seismic Hazards in California." In addition, all engineering practices, and analyses of structural design shall be consistent with SFBC standards to ensure seismic stability, including reduction of potential landslide hazards.*
- *DBI shall employ a third-party CEG and California Registered Professional Engineer (Civil) (PE) to form a Geotechnical Peer Review Committee (GPRC), consisting of DBI and these third-party reviewers. The GPRC shall review the site-specific geotechnical investigations and the site-specific structural, foundation, infrastructure, and other relevant plans to ensure that these plans incorporate all necessary geotechnical mitigation measures. No permits shall be issued by DBI until the GPRC has approved the geotechnical investigation and the Project plans, including the factual determinations and the proposed engineering designs and construction methods.*

---

[422] CGS, 2000.

[423] Geogrids are synthetic fabrics (fiberglass, polyester, treated steel, etc.) formed into nets with openings more than ¼ inch in size to allow the fabric to interlock with surrounding soil, rock, and other below-ground-level materials and to function as reinforcement.

- *All Project structural designs shall incorporate and conform to the requirements in the site-specific geotechnical investigations.*
- *The site-specific Project plans shall incorporate the mitigation measures contained in the approved site-specific geotechnical reports to reduce landslide hazards. The engineering design techniques to reduce landslide hazards shall include proven methods generally accepted by California Certified Engineering Geologists, subject to DBI and GPRC review and approval. The design-level geologic and geotechnical studies shall identify the presence of landslides and potentially unstable slopes and shall identify means to avoid the hazard or support the design of engineering procedures to stabilize the slopes, as required by Chapter 18 (Soils and Foundations) of the SFBC, as well as the procedures outlined in CGS Special Publication 117A. SFBC Sections 1803 through 1812 contain the formulae, tables, and graphs by which the Project engineer shall develop the Project's slope-stability specifications, including the appropriate foundation designs for structures on slopes and which would be used by DBI to verify the applicability of the specifications. If the presence of unstable slopes is identified, appropriate support and protection procedures shall be designed and implemented to maintain the stability of slopes adjacent to newly graded or re-graded access roads, work areas, and structures during and after construction, and to minimize potential for damage to structures and facilities at the Project site. These stabilization procedures, including, but not necessarily limited to, the following:*
  - *Retaining walls, rock buttresses, screw anchors, or concrete piers*
  - *Slope drainage or removal of unstable materials*
  - *Rockfall catch fences, rockfall mesh netting, or deflection walls*
  - *Setbacks at the toe of slopes*
  - *Avoidance of highly unstable areas*
- *The Project CEG or GE shall be responsible for ensuring compliance with these requirements.*

Implementation of this measure would ensure that hazards caused by the potential effects of seismically induced landslides would be less than significant.

Alice Griffith Public Housing

Given its proximity to Bayview Hill, the Alice Griffith Housing site could be exposed to the risks of landslides. New development on the Alice Griffith Public Housing site would be subject to HUD approval and Executive Order 12699. The new development would be subject to the SFBC, which would meet the requirements of the Executive Order. The San Francisco Department of Building Inspection (DBI) would be the agency responsible for implementing and enforcing appropriate seismic design and construction standards for the new development. DBI would be the City's responsible agency. Federal implementation and enforcement of the seismic safety program would be achieved through notification by the City to the building owner, architect, engineer, or contractor of the required minimum standards and requiring written acknowledgement of awareness of the requirements and of intent to comply.

HUD could require some form of compliance certification, such as the engineer's and architect's signed and stamped verification of seismic design codes, standards, and practices used in the design and construction of the buildings, or submittal of Planning Department and/or DBI permit review and inspection documents HUD. Compliance with mitigation measure MM GE-4a.2 would ensure that all appropriate documentation is submitted to the HUD, if requested. Implementation of this mitigation, as

well as mitigation measure MM GE-6a, would ensure that the impact to Alice Griffith Housing from seismically induced landslides would be less than significant.

Yosemite Slough Bridge

The potential for exposure of the Yosemite Slough bridge to adverse effects caused by seismically induced landslides would be unlikely because of the low-lying topography in the vicinity of the bridge. There are no mapped seismically induced landslides areas on the Project site or near the slough. Therefore, there would be no impact on the Yosemite Slough bridge caused by seismically induced landslides.

Impact of Hunters Point Shipyard Phase II

Impact GE-6b **Implementation of the Project at HPS Phase II would not expose people or structures to substantial adverse effects caused by seismically induced landslides. (No Impact) *[Criterion L.a(iv)]***

As shown in Figure III.L-3, seismically induced landslides in the HPS Phase II site exist in the areas uphill from the Project boundaries where serpentinite is abundant in the shear zone. A few small landslide hazards exist in a large serpentinite block of the Hunters Point Shear Zone, between Innes Avenue and Crisp Road, northwest of HPS Phase II.[424] Slopes adjacent to the Phase II site have been rebuilt as subdrained engineered slopes during ongoing Phase I development, and any remaining areas of potential landslide hazards are outside the reach of the Phase II boundaries. Therefore, there would be no impact caused by seismically induced landslides. No mitigation is required.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-6 **Implementation of the Project would not expose people or structures to substantial adverse effects caused by seismically induced landslides. (Less than Significant with Mitigation) *[Criterion L.a(iv)]***

The potential for adverse effects due to seismically induced landslides exists at the Project site. Implementation of mitigation measures MM GE-6a and MM GE-4a.2 would ensure compliance with the SFBC and any special requirements of the HUD for compliance documentation and would reduce potential impacts from landslides a less-than-significant level.

Impact GE-7: Shoreline Instability

Impact of Candlestick Point

Impact GE-7a **Implementation of the Project at Candlestick Point would not expose people or structures to substantial adverse effects caused by shoreline instability. (Less than Significant with Mitigation) *[Criterion L.c]***

The shoreline along Candlestick Point consists of slopes protected by rip-rap or concrete debris and several areas of unprotected, beach-fronted slopes, exposed mudflats, and vegetation. Along the majority of the south-facing shoreline, active erosion exists. Stabilization of the Candlestick Point shoreline would include the placement of additional (rock) riprap to improve the existing rip-rap edge on most of the Northern,

[424] CGS, Seismic Hazard Zone Map, CCSF, November 2000.

Eastern, and Southern shoreline; the creation of new tidal habitat in two reaches of natural edge on the Northern shoreline by laying back the slope to a flatter configuration and adding marsh plantings; and the creation of a sandy recreational beach at the mid-point of the Wind Meadow reach along the Eastern Shoreline by laying the slope back at a 6H:1V or flatter configuration. In addition to improvements to shoreline features, and to reduce the potential for a future rise in sea level that could adversely affect the Project site, the Project includes modification of the land surface through grading and the importation of fill. These modifications would raise the surface elevation by 36 inches above the 100-year base flood elevation and building finish floor elevations would be 6 inches above that (total of 42 inches above Base Flood Elevation) per mitigation measure MM HY-12a.1 to account for future sea level rise, and include an adaptive management strategy that would provide further protection for future sea level rise of 55 inches or more if this should become necessary. These improvements are intended to, will be designed to, and, therefore, would improve the stability of the shoreline. Therefore, the Project would not result in exposure of structures and facilities at Candlestick Point to substantial adverse effects caused by shoreline instability. The impact would be less than significant.

Impact of Hunters Point Shipyard Phase II

Impact GE-7b **Implementation of the Project at HPS Phase II would not expose people or structures to substantial adverse effects caused by shoreline instability. (Less than Significant with Mitigation) *[Criterion L.c]***

The existing shoreline along the HPS Phase II site consists of rip-rap protected slopes, unprotected embankments fronted by beach, concrete submarine dry-docks, pile-supported wharves, some of which are failing, quay-walls, concrete bulkheads, timber decking and piles, and dilapidated piers. Most of the naval structures are in deteriorated condition. In some areas of the HPS Phase II shoreline, piers and wharfs have deteriorated from lack of maintenance and near-shore settlement has occurred, resulting in damage to seawall structures. Repairs of existing HPS Phase II seawall structures would involve replacement of piles and tie-back systems and replacement of eroded fill material behind seawall structures. In some locations, placement of buttress fill (below the water surface) would be needed to enhance structural stability of some seawall structures. At the submarine drydocks in Parcels B and C, the concrete bulkheads would be left in place, but disconnected from the shoreline by demolishing the near-shore sections to prevent public access. Slope stability would be improved by placing rock or sand buttresses along the quay-wall, applying high strength concrete grout to exposed surfaces and/or epoxy mix application to cracks as needed, and installing weep-holes above low tide elevation to relieve the loading from the fill to be placed along the shoreline. At the berths and wharves in Parcels B, C, D, and E, new steel sheet pile bulkheads would be constructed behind the existing corroded bulkheads; reinforced concrete beams, deck slabs and steel caisson piles would be repaired; the upper 10 to 15 feet of the concrete wall facing, as well as the timber cribbing and bank rock fill would be removed and the facing sloped back at a 2H:1V slope and protected with rock facing to provide a more natural-looking surface without any additional bayfill. The modification of the drydocks, berths, and wharves would preclude public access, thereby creating opportunities for waterbirds to roost on the retained portions of these structures. In addition to improvements to shoreline features, and to reduce the potential for a future rise in sea level that could adversely affect the Project site, the Project includes modification of the land surface through grading and the importation of fill. These modifications would raise the surface elevation by 36 inches above the 100-year base flood elevation and building finish floor elevations would be 6 inches above that

(total of 42 inches above Base Flood Elevation) per mitigation measure MM HY-12a.1 to account for future sea level rise and include an adaptive management strategy that would provide further protection for future sea level rise up to 55 inches if this should become necessary. These improvements are intended to, will be designed to, and, therefore, would improve the stability of the shoreline. Therefore, the Project would not result in exposure of structures and facilities at HPS Phase II to substantial adverse effects caused by shoreline instability. The impact would be less than significant.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-7 **Implementation of the Project would not expose people or structures to substantial adverse effects caused by shoreline instability. (Less than Significant with Mitigation) *[Criterion L.c]***

The existing shoreline exhibits active erosion and consists of areas of unprotected slopes and dilapidated naval pier and wharf structures. The Project would make numerous shoreline improvements, including additional rip-rap, creation of new beach and tidal habitat, and some grading and importation of fill at certain locations. These modifications would raise the surface elevation by 36 inches above the 100-year base flood elevation and building finish floor elevations would be 6 inches above that (total of 42 inches above Base Flood Elevation) per mitigation measure MM HY-12a.1 to account for future sea level rise and include an adaptive management strategy that would provide further protection for future sea level rise up to 55 inches if this should become necessary. These improvements are intended to, will be designed to, and, therefore, would improve the stability of the shoreline. Therefore, the Project would not result in exposure of structures and facilities at the Project site to substantial adverse effects caused by shoreline instability. The impact would be less than significant.

Impact GE-8: Landslides

Impact of Candlestick Point

Impact GE-8a **Implementation of the Project at Candlestick Point would not expose people or structures to substantial adverse effects caused by landslides. (Less than Significant with Mitigation) *[Criterion L.c]***

Candlestick Point

The Candlestick Point site, including the Alice Griffith Public Housing site, could be exposed to landslide hazards. Upland areas are most susceptible to landslides. Heavy rainfall contributes to this risk when soil becomes saturated. Site-specific geotechnical investigations would be required, and appropriate support and protection procedures would be designed and implemented for any identified unstable slopes.

Design and construction of the structures and facilities of the Project would incorporate appropriate engineering practices to ensure slope stability, as required by Chapter 16 (Structural Design) and Chapter 18 (Soils and Foundations) of the SFBC. Sections 1607 through 1614 contain the formulae, tables, and graphs by which the Project engineer would develop the structural specifications for building design and which would be used by DBI to verify the applicability of the specifications. Sections 1804 through 1812 contain similar information for the design and verification of adequate soils and foundation support for a project. Section 1802 requires the use of this information in the site-specific geotechnical

analyses of the Project site. Implementation of mitigation measure MM GE-6a would ensure that risks to structures from landslides would be avoided or reduced a less-than-significant level.

Yosemite Slough Bridge

The potential for exposure of the Yosemite Slough bridge to substantial adverse effects caused by landslides would be unlikely because of the low-lying topography in the location of the bridge. Therefore, there would be no impact to the Yosemite Slough bridge caused by landslides.

Impact of Hunters Point Shipyard Phase II

Impact GE-8b **Implementation of the Project at HPS Phase II would not expose people or structures to substantial adverse effects caused by landslides. (Less than Significant with Mitigation) *[Criterion L.c]***

The potential for exposure to adverse effects caused by landslides in the HPS Phase II site exists in the upland areas of the shoreline where serpentinite is abundant in the shear zone. Heavy rainfall contributes to this risk when soil becomes saturated. Slopes adjacent to the HPS Phase II site were rebuilt as subdrained engineered slopes during ongoing Phase I development. Any remaining areas of mapped potential landslide hazards are outside the HPS Phase II boundaries.

If the presence of unstable slopes were identified during preparation of the site-specific geotechnical investigations, appropriate support and protection procedures would be designed and implemented, as required by mitigation measure MM GE-6a to maintain the stability of slopes adjacent to newly graded or re-graded access roads, work areas, and structures during and after construction, and to minimize potential for damage to structures and facilities in the HPS Phase II site. Sections 1803 through 1812 contain the formulae, tables, and graphs by which the Project engineer would develop the Project's slope-stability specifications, including the appropriate foundation designs for structures on slopes and which would be used by DBI to verify the applicability of the specifications. Implementation of mitigation measure MM GE-6a would ensure that risks to structures in HPS Phase II from landslides would be avoided or reduced a less-than-significant level.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-8 **Implementation of the Project would not expose people or structures to substantial adverse effects caused by landslides. (Less than Significant with Mitigation) *[Criterion L.c]***

The potential for adverse effects caused by landslides exists at the Project site. Site-specific, design-level geotechnical investigations would be required to be submitted to DBI in connection with permit applications for individual Project elements, as specified in mitigation measure MM GE-6a. The site-specific analyses must assess these conditions and prescribe the requirements for foundations on slopes in accordance with the SFBC. All geotechnical investigations and permits must be approved by DBI. With implementation of this mitigation, the Project's impact with regard to landslides would be less than significant.

Impact GE-9: Soil Hazards—Settlement

Impact of Candlestick Point

Impact GE-9a **Implementation of the Project at Candlestick Point, including Alice Griffith Housing and the Yosemite Slough bridge, would not expose people or structures to substantial adverse effects caused by damage from settlement. (Less than Significant with Mitigation) *[Criterion L.c]***

Candlestick Point

The Candlestick Point site could be exposed to settlement hazards. Unstable subsurface materials, such as artificial fill or soft Bay Mud deposits, are abundant in the Candlestick Point site (refer to Figure III.L-1). Slight to severe damage to structures could be caused by the settlement of poorly compacted fill or consolidation of very soft natural deposits. Extensive Young Bay Mud deposits are predominant in the eastern half of the site toward the shoreline. The rate of settlement of the Young Bay Mud from the load of the artificial fill is now very small, but further increase in loads, whether resulting from placement of new fill or the construction of buildings, would initiate a new cycle of consolidation settlement.[425,426] The Young Bay Mud is underlain by firmer soils and bedrock that do not pose settlement hazards.

Site grades would need to be raised over most of the Project site in order to reach minimum final grades and to compensate for settlement caused by densification during ground improvements and Young Bay Mud consolidation and secondary compression settlement caused by fill and building loads. Settlement in response to new loads would occur at rates similar to those that have occurred historically. Based on past observations, settlement caused by new loads could continue for a period of 5 to 50 years (or more) unless mitigated by surcharging, as explained below.

Where the site is underlain by an extensive zone of Young Bay Mud, consolidation settlements could be accelerated by use of surcharging, thereby allowing much of the future settlement to occur prior to construction of new improvements. Surcharging involves adding excess fill, for a limited period of time, above the elevation that is needed to achieve the intended final site grades. Prefabricated vertical drains (wick drains) can be used to decrease surcharge durations by increasing lateral soil drainage and allowing settlement that normally would occur over years to occur in months. Wick drains probably would be needed in most areas of the Project site because the development schedule probably would not allow for longer surcharge durations.

Surcharging can be used to reduce the settlements that result from net building loads. If the net building loads do not increase the stresses in the clay soils beyond those to which they have been consolidated previously under a surcharge load, the resulting settlements would be much smaller than they would be otherwise. When a soil has been loaded previously to a greater stress than the current stress, it is said to be over-consolidated. Over-consolidation reduces secondary compression. Consequently, surcharging offers three benefits: (1) the settlement that results from placement of new fill would be expedited; (2) the primary

[425] ENGEO, 2009.
[426] Engineering/Remediation Resources Group, Inc. and Shaw Environmental, Inc., 2009.

settlement caused by new building loads would be reduced; and (3) long-term settlements caused by secondary compression would be reduced.

Further secondary compression would occur following primary consolidation. Design-level studies must be conducted to better estimate the expected amounts of secondary compression and to evaluate the effectiveness of surcharging to reduce secondary compression.

Design and construction of structures and facilities in the Candlestick Point site would incorporate appropriate engineering practices, as required by Chapter 16 (Structural Design) and Chapter 18 (Soils and Foundations) of the SFBC. Sections 1607 through 1614 contain the formulae, tables, and graphs by which the Project engineer would develop the structural specifications for building design and which would be used by DBI to verify the applicability of the specifications. Sections 1804 through 1812 contain similar information for the design and verification of adequate soils and foundation support for a project. Section 1802 requires the use of this information in the soils analyses of the Project site.

Where shallow foundations would be underlain by poorly compacted artificial fill that may be subject to static settlement, it could be possible to employ a combination of removal and recompaction with the placement of geogrid beneath structures to help distribute differential settlement that might occur. Mid-rise and high-rise structures probably would be founded on deep foundations bearing in strata below the poorly compacted fill and soft Bay Mud deposits with flexible utility connections to allow some settlement beneath the buildings. If settlement estimates were such that the previously described treatments would not suffice, procedures outlined in mitigation measure MM GE-5a would avoid this impact or reduce it a less-than-significant level.

Selection of the appropriate ground improvement techniques would be dependent on the land use, development type, soil profile, and estimated settlement, as outlined previously in Table III.L-7 and Table III.L-8.[427] Implementation of mitigation measure MM GE-5a would ensure Project compliance with the requirements of the SFBC and would ensure that potential impacts from unstable subsurface soils would be less than significant.

Alice Griffith Public Housing

The Alice Griffith Public Housing site could be exposed to settlement hazards. New development on the Alice Griffith Public Housing site would be subject to HUD approval and Executive Order 12699. The new development would be subject to the SFBC, which would meet the requirements of the Executive Order. The San Francisco Department of Building Inspection (DBI) would be the agency responsible for implementing and enforcing appropriate seismic design and construction standards for the new development. DBI would be the City's responsible agency. Federal implementation and enforcement of the seismic safety program would be achieved through notification by the City to the building owner, architect, engineer, or contractor of the required minimum standards and requiring written acknowledgement of awareness of the requirements and of intent to comply.

HUD could require some form of compliance certification, such as the engineer's and architect's signed and stamped verification of seismic design codes, standards, and practices used in the design and construction of

[427] ENGEO, 2009.

the buildings, or submittal of Planning Department and/or DBI permit review and inspection documents to HUD. Compliance with mitigation measure MM GE-4a.2 would ensure that all appropriate documentation is submitted to HUD, if requested. Implementation of this mitigation and MM GE-5a would ensure that the impact to Alice Griffith Housing from settlement would be less than significant.

Yosemite Slough Bridge

The Yosemite Slough bridge could be exposed to settlement hazards. Unstable subsurface materials, such as artificial fill or soft Bay Mud deposits are abundant in the Candlestick Point site (refer to Figure III.L-1). Slight to severe damage to structures could occur caused by the settlement of poorly compacted fill or consolidation of very soft natural deposits.

Design and construction of the bridge would incorporate appropriate engineering practices, as required by BOE Standard Specifications Part 4 (Structures) and Part 7 (Excavation, Backfill, and Embankment) and would be based on Caltrans specifications. Implementation of mitigation measure MM GE-4a.3, would ensure that the design of the bridge would be based on Caltrans specifications (*Bridge Design Specifications*, Sections 3, 4, 5, and 23 of *Bridge Memos to Designers*), and would meet the BOE requirements. Implementation of mitigation measures MM GE-5a and MM GE-4a.3 would ensure the potential damage from unstable subsurface soils would be less than significant.

Impact of Hunters Point Shipyard Phase II

Impact GE-9b **Implementation of the Project at HPS Phase II would not expose people or structures to substantial adverse effects caused by damage from settlement. (Less than Significant with Mitigation) *[Criterion L.c]***

The potential for exposure to adverse effects caused by settlement in the HPS Phase II site exists. Poorly consolidated artificial fill deposits are abundant in the HPS Phase II site. Slight to severe damage to structures could occur caused by the settlement of poorly compacted fill or consolidation of very soft natural deposits. Extensive Young Bay Mud deposits are predominant in Parcels D and E. The rate of settlement of the Young Bay Mud from the load of the artificial fill is now very small, but any increase in loads, whether resulting from placement of new fill or the construction of buildings, would initiate a new cycle of consolidation settlement.[428,429] The Young Bay Mud is underlain by firmer soils and bedrock that are not subject to settlement hazards. Where the site is underlain by Young Bay Mud subject to consolidation settlements under new fill loads, the planned development primarily includes open space and parking areas. These areas generally could tolerate a greater amount of consolidation settlement without serious risk because there would be no major structures or utilities to be affected. Gravity utilities can be designed to accommodate a certain amount of planned settlement.

Design and construction of structures and facilities in the HPS Phase II site would incorporate appropriate engineering practices, as required by Chapter 16 (Structural Design) and Chapter 18 (Soils and Foundations) of the SFBC. Sections 1607 through 1614 contain the formulae, tables, and graphs by which the Project engineer would develop the structural specifications for building design and which would be used by DBI to verify the applicability of the specifications. Sections 1804 through 1812 contain similar

[428] ENGEO, 2009.

[429] Engineering/Remediation Resources Group, Inc. and Shaw Environmental, Inc., 2009.

information for the design and verification of adequate soils and foundation support for a project. Section 1802 requires the use of this information in the soils analyses of the Project site.

Where shallow foundations would be underlain by poorly compacted artificial fill that may be subject to static settlement, it could be possible to employ a combination of removal and recompaction with the placement of geogrid beneath structures to help distribute differential settlement that might occur. Mid-rise and high-rise structures probably would be founded on deep foundations bearing in strata below the poorly compacted fill and soft Bay Mud deposits with flexible utility connections to allow some settlement beneath the buildings. If settlement estimates were such that the previously described treatments would not suffice, procedures outlined in mitigation measure MM GE-5a would avoid this impact or reduce it a less-than-significant level.

Selection of the appropriate ground improvement techniques would be dependent on the land use, development type, soil profile, and estimated settlement, as outlined previously in Table III.L-7 and Table III.L-8.[430] Implementation of mitigation measure MM GE-5a would ensure Project compliance with the requirements of the SFBC and would ensure that potential impacts from unstable subsurface soils would be less than significant.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-9 **Implementation of the Project would not expose people or structures to substantial adverse effects caused by damage from settlement. (Less than Significant with Mitigation) *[Criterion L.c]***

The potential for adverse effects due to settlement exists at the Project site. However, design-level geotechnical investigations must evaluate the structural design, as required by the SFBC through review by DBI. Implementation of mitigation measures MM GE-5a, MM GE-4a.2, and MM GE-4a.3 would ensure compliance with the provisions of the SFBC and would reduce the impact a less-than-significant level.

Impact GE-10: Soil Hazard—Expansive Soils

Impact of Candlestick Point

Impact GE-10a **Implementation of the Project at Candlestick Point, including Alice Griffith Housing and the Yosemite Slough bridge, would not expose people or structures to substantial adverse effects caused by expansive soils. (Less than Significant with Mitigation) *[Criterion L.d]***

Candlestick Point

The Candlestick Point site could be exposed to expansive soil hazards, which can cause damage to structures, foundations and buried utilities and can increase required maintenance. Expansion and contraction of soils in response to changes in moisture content can cause differential and cyclical movements that can cause damage and/or distress to structures and equipment.

[430] ENGEO, 2009.

Soils at the Candlestick Point site are predominantly Orthents, cut and fill, Urban land and Urban land Orthents, with some Barnabe-Candlestick complex soils in the upland areas. These soils have various levels of risk for expansion.[431] Impacts related to expansive soils would be avoided or reduced a less-than-significant level for structures and facilities in the Candlestick Point site through the implementation of standard engineering and geotechnical practices for the identification and remediation of expansive soils, as required by Chapter 18 (Soils and Foundations) of the SFBC.

To avoid or reduce the potential impact from expansive soils at the Candlestick Point site, the following mitigation shall be implemented:

MM GE.10a *Site-Specific Geotechnical Investigation with Expansive Soils Analyses. Prior to issuance of building permits for the Project site:*

- *The Applicant shall submit to the San Francisco Department of Building Inspection (DBI) for review and approval a site-specific, design-level geotechnical investigation prepared by a California Certified Engineering Geologist (CEG) or California Registered Geotechnical Engineer (GE), as well as project plans prepared in compliance with the requirements of the San Francisco Building Code (SFBC). In addition, all engineering practices, and analyses of structural design shall be consistent with SFBC standards to ensure soils stability, including reduction of potential soil expansion hazards.*
- *DBI shall employ a third-party CEG and California Registered Professional Engineer (Civil) (PE) to form a Geotechnical Peer Review Committee (GPRC), consisting of DBI and these third-party reviewers. The GPRC shall review the site-specific geotechnical investigations and the site-specific structural, foundation, infrastructure, and other relevant plans to ensure that these plans incorporate all necessary geotechnical mitigation measures. No permits shall be issued by DBI until the GPRC has approved the geotechnical investigation and the Project plans, including the factual determinations and the proposed engineering designs and construction methods.*
- *All Project structural designs shall incorporate and conform to the requirements in the site-specific geotechnical investigations.*
- *The site-specific Project plans shall incorporate the mitigation measures contained in the approved site-specific geotechnical reports to reduce expansive soils hazards. The engineering design techniques to reduce expansive soils hazards shall include proven methods generally accepted by California Certified Engineering Geologists, subject to DBI and GPRC review and approval. The design-level geologic and geotechnical studies shall identify the presence of expansive soils and potentially unstable soils and shall identify means to avoid the hazard or support the design of engineering procedures to stabilize the soils, as required by Chapter 18 (Soils and Foundations) of the SFBC. SFBC Sections 1803 through 1812 contain the formulae, tables, and graphs by which the Project engineer shall develop the Project's soil-stability specifications, including the appropriate foundation designs for structures on expansive soils and which would be used by DBI to verify the applicability of the specifications. If the presence of expansive soils is identified, appropriate support and protection procedures shall be designed and implemented to maintain the stability of soils adjacent to newly graded or re-graded access roads, work areas, and structures during and after construction, and to minimize potential for damage to structures and facilities at the Project site.*
- *The Project CEG or GE shall be responsible for ensuring compliance with these requirements.*

[431] NRCS (accessed April 2008).

Implementation of this measure would ensure that hazards caused by the potential effects of expansive soils would be less than significant.

Alice Griffith Public Housing

The Alice Griffith Public Housing site could be exposed to hazards from expansive soils. New development on the Alice Griffith Public Housing site would be subject to HUD approval and Executive Order 12699. The new development would be subject to the SFBC, which would meet the requirements of the Executive Order. The San Francisco Department of Building Inspection (DBI) would be the agency responsible for implementing and enforcing appropriate seismic design and construction standards for the new development. DBI would be the City's responsible agency. Federal implementation and enforcement of the seismic safety program would be achieved through notification by the City to the building owner, architect, engineer, or contractor of the required minimum standards and requiring written acknowledgement of awareness of the requirements and of intent to comply.

HUD could require some form of compliance certification, such as the engineer's and architect's signed and stamped verification of seismic design codes, standards, and practices used in the design and construction of the buildings, or submittal of Planning Department and/or DBI permit review and inspection documents to HUD. Compliance with mitigation measure MM GE-4a.2 would ensure that all appropriate documentation is submitted to HUD, if requested. Implementation of this mitigation, as well as MM GE-10a, would ensure that the impact to Alice Griffith Housing from expansive soils would be less than significant.

Yosemite Slough Bridge

The Yosemite Slough bridge could be exposed to expansive soil hazards, which can cause damage to structures, foundations and buried utilities and can increase required maintenance. Expansion and contraction of soils in response to changes in moisture content can cause differential and cyclical movements that can cause damage and/or distress to structures and equipment.

Soils at Candlestick Point are predominantly Orthents, cut and fill, Urban Land and Urban Land Orthents. These soils have various levels of risk for expansion.[432] Impacts related to expansive soils would be rendered less than significant for the bridge through the implementation of standard engineering and geotechnical practices for the identification and remediation of expansive soils, as required by BOE Standard Specifications Part 7 (Excavation, Backfill, and Embankment). The design of the bridge would be based on Caltrans specifications, as required by mitigation measure MM GE-4a.3. Implementation of mitigation measures MM GE-10a and MM GE-4a.3 would reduce the impact from expansive soils on the Yosemite Slough bridge a less-than-significant level.

[432] NRCS (accessed April 2008).

Impact of Hunters Point Shipyard Phase II

Impact GE-10b **Implementation of the Project at HPS Phase II would not expose people or structures to substantial adverse effects caused by expansive soils. (Less than Significant with Mitigation) *[Criterion L.d]***

The HPS Phase II site has the potential to expose Project improvements to adverse effects caused by expansive soils. Expansive soils can cause damage to structures, foundations and buried utilities and can increase required maintenance. Expansion and contraction of soils in response to changes in moisture content can cause differential and cyclical movements that can cause damage and/or distress to structures and equipment.

Soils at HPS Phase II are predominantly Orthents, cut and fill, Urban land and Urban land Orthents, with some Barnabe-Candlestick complex soils in the upland areas. These soils have various levels of risk for expansion.[433] Impacts related to expansive soils would be avoided or reduced a less-than-significant level for structures and facilities in the HPS Phase II site through the implementation of standard engineering and geotechnical practices for the identification and remediation of expansive soils, as required by Chapter 18 (Soils and Foundations) of the SFBC. Implementation of mitigation measure MM GE-10a would avoid or reduce the impact to structures and facilities at HPS Phase II from expansive soils a less-than-significant level by ensuring compliance with the SFBC.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-10 **Implementation of the Project would not expose people or structures to substantial adverse effects caused by expansive soils. (Less than Significant with Mitigation) *[Criterion L.d]***

The potential for adverse effects caused by expansive soils exists at the Project site. Design-level geotechnical investigations must evaluate the structural design, as required by the SFBC through review by DBI. Implementation of mitigation measures MM GE-10a, MM GE-4a.1, MM GE-4a.2, and MM GE-4a.3 would avoid or reduce the impact to Project structures from expansive soils a less-than-significant level.

Impact GE-11; Soil Hazard—Corrosive Soils

Impact of Candlestick Point

Impact GE-11a **Implementation of the Project at Candlestick Point, including Alice Griffith Housing and the Yosemite Slough bridge, would not expose people or structures to substantial adverse effects caused by corrosive soils. (Less than Significant with Mitigation) *[Criterion L.c]***

Candlestick Point

Structures at Candlestick Point could be exposed to corrosive soil hazards. Problematic soils, including corrosive minerals and corrosive saline groundwater, can cause damage to structures, foundations and buried utilities, and can increase maintenance needs. Depending on the degree of corrosivity of subsurface

[433] NRCS (accessed April 2008).

soils, concrete and reinforcing steel in concrete structures and bare-metal structures exposed to these soils can deteriorate, eventually leading to structural failure.

Soils at Candlestick Point are predominantly Orthents, cut and fill, Urban land and Urban land Orthents, with some Barnabe-Candlestick complex soils in the upland areas. These soils have a moderate risk of soil corrosivity to concrete and steel.[434] Impacts related to corrosive soils would be rendered less than significant for structures and facilities in the Candlestick Point site through the implementation of standard engineering and geotechnical practices for the identification and remediation of corrosive soils, as required by Chapter 18 (Soils and Foundations) of the SFBC.

MM GE-11a *Site-Specific Geotechnical Investigation with Corrosive Soils Analyses. Prior to issuance of building permits for the Project site:*

- *The Applicant shall submit to the San Francisco Department of Building Inspection (DBI) for review and approval a site-specific, design-level geotechnical investigation prepared by a California Certified Engineering Geologist (CEG) or California Registered Geotechnical Engineer (GE), as well as project plans prepared in compliance with the requirements of the San Francisco Building Code (SFBC). In addition, all engineering practices, and analyses of structural design shall be consistent with SFBC standards to ensure soils stability, including reduction of potential hazards from corrosive soils.*
- *DBI shall employ a third-party CEG and California Registered Professional Engineer (Civil) (PE) to form a Geotechnical Peer Review Committee (GPRC), consisting of DBI and these third-party reviewers. The GPRC shall review the site-specific geotechnical investigations and the site-specific structural, foundation, infrastructure, and other relevant plans to ensure that these plans incorporate all necessary geotechnical mitigation measures. No permits shall be issued by DBI until the GPRC has approved the geotechnical investigation and the Project plans, including the factual determinations and the proposed engineering designs and construction methods.*
- *All Project structural designs shall incorporate and conform to the requirements in the site-specific geotechnical investigations.*
- *The site-specific Project plans shall incorporate the mitigation measures contained in the approved site-specific geotechnical reports to reduce potential hazards from corrosive soils. The engineering design techniques to reduce corrosive soils hazards shall include proven methods generally accepted by California Certified Engineering Geologists, subject to DBI and GPRC review and approval. The design-level geologic and geotechnical studies shall identify the presence of corrosive soils and shall identify means to avoid the hazard, as required by Chapter 18 (Soils and Foundations) of the SFBC. SFBC Sections 1803 through 1812 contain the formulae, tables, and graphs by which the Project engineer shall develop the Project's structural design specifications, including the appropriate foundation designs for structures on corrosive soils and which would be used by DBI to verify the applicability of the specifications. If the presence of corrosive soils is identified, appropriate protection procedures shall be designed and implemented to minimize potential for damage from corrosive soils to structures and facilities at the Project site.*
- *The Project CEG or GE shall be responsible for ensuring compliance with these requirements.*

Implementation of mitigation measure MM GE-11a would ensure compliance with the requirements of the SFBC and would avoid or reduce the potential for damage from corrosive soils a less-than-significant level.

[434] NRCS (accessed April 2008).

Alice Griffith Public Housing

New development at the Alice Griffith Public Housing site could be exposed to corrosive soil hazards. New development on the Alice Griffith Public Housing site would be subject to HUD approval and Executive Order 12699. The new development would be subject to the SFBC, which would meet the requirements of the Executive Order. The San Francisco Department of Building Inspection (DBI) would be the agency responsible for implementing and enforcing appropriate seismic design and construction standards for the new development. DBI would be the City's responsible agency. Federal implementation and enforcement of the seismic safety program would be achieved through notification by the City to the building owner, architect, engineer, or contractor of the required minimum standards and requiring written acknowledgement of awareness of the requirements and of intent to comply.

As the HUD lead agency, the Mayor's Office of Housing could require some form of compliance certification, such as the engineer's and architect's signed and stamped verification of seismic design codes, standards, and practices used in the design and construction of the buildings, or submittal of Planning Department and/or DBI permit review and inspection documents to the Mayor's Office of Housing. Compliance with mitigation measure MM GE-4a.2 would ensure that all appropriate documentation is submitted to the Mayor's Office of Housing, if requested. Implementation of this mitigation and MM GE-11a would ensure that the impact to Alice Griffith Housing from corrosive soils would be less than significant.

Yosemite Slough Bridge

The Yosemite Slough bridge could be exposed to corrosive soil hazards. Problematic soils, including corrosive minerals and corrosive saline groundwater, can cause damage to structures, foundations and buried utilities and can increase required maintenance. Depending on the degree of corrosivity of subsurface soils, concrete and reinforcing steel in concrete structures and bare-metal structures exposed to these soils can deteriorate, eventually leading to structural failure.

Soils in the proposed Candlestick Point site are predominantly Orthents, cut and fill, Urban land and Urban land Orthents. These soils have a moderate risk of soil corrosivity to concrete and steel.[435] Impacts related to corrosive soils would be rendered less than significant for the bridge through the implementation of standard engineering and geotechnical practices for the identification and remediation of corrosive soils, as required by BOE Standard Specifications Part 7 (Excavation, Backfill, and Embankment). The design of the bridge would be based on Caltrans specifications, as required by mitigation measure MM GE-4a.3. Implementation of mitigation measures MM GE-11a and MM GE-4a.3 would reduce the impact from corrosive soils on the Yosemite Slough bridge a less-than-significant level.

[435] NRCS (accessed April 2008).

Impact of Hunters Point Shipyard Phase II

Impact GE-11b **Implementation of the Project at HPS Phase II would not expose people or structures to substantial adverse effects caused by corrosive soils. (Less than Significant with Mitigation) *[Criterion L.c]***

Structures at HPS Phase II could be exposed to corrosive soil hazards. Problematic soils, including corrosive minerals and corrosive saline groundwater, can cause damage to structures, foundations and buried utilities and can increase required maintenance. Depending on the degree of corrosivity of subsurface soils, concrete and reinforcing steel in concrete structures and bare-metal structures exposed to these soils can deteriorate, eventually leading to structural failure.

Soils in the HPS Phase II site are predominantly Orthents, cut and fill, Urban Land and Urban Land Orthents, with some Barnabe-Candlestick complex soils in the upland areas. These soils have a moderate risk of soil corrosivity to concrete and steel.[436] Impacts related to corrosive soils would be rendered less than significant for structures and facilities in the HPS Phase II site through the implementation of standard engineering and geotechnical practices for the identification and remediation of corrosive soils, as required by Chapter 18 (Soils and Foundations) of the SFBC. Implementation of mitigation measure MM GE-11a would ensure compliance with the requirements of the SFBC and would avoid or reduce the impact on structures and facilities in HPS Phase II a less-than-significant level.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact GE-11 **Implementation of the Project would not expose people or structures to substantial adverse effects caused by corrosive soils. (Less than Significant with Mitigation) *[Criterion L.c]***

The potential for adverse effects caused by corrosive soils exists at the Project site. Design-level geotechnical investigations must evaluate the structural design, as required by the SFBC through review by DBI. Implementation of mitigation measures MM GE-11a, MM GE-4a.2, and MM GE-4a.3 would avoid or reduce the impact to Project structures from corrosive soils a less-than-significant level.

Impact GE-12: Surface Fault Rupture

Impact GE-12 **Implementation of the Project would not expose people or structures to substantial adverse effects caused by surface fault rupture. (No Impact) *[Criterion L.a(i)]***

Fault rupture hazards in the Project site are unlikely. Ground rupture occurs most commonly along preexisting faults, which are zones of weakness, but can occur slowly as fault creep or more suddenly as the result of major stress release along the fault plane (earthquakes). Where rupture occurs near buildings or other facilities, there is a potential for injury to persons and significant economic loss because of structural damage.

[436] NRCS (accessed April 2008).

The Hunters Point shear zone, north of Candlestick Point, is considered inactive. No known active faults cross the Project site, making hazards from fault rupture unlikely.[437] Therefore, there would be no impact caused by surface fault rupture. No mitigation is required.

Impact GE-13: Septic Tanks or Alternative Wastewater Disposal Systems

Impact GE-13 **Implementation of the Project would not result in the use of soils incapable of adequately supporting septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater. (No Impact) *[Criterion L.e]***

The Project would be connected to the City's existing wastewater treatment and disposal system. Development of the Project would not involve the use of septic tanks or alternative wastewater disposal systems. No impact would occur. No mitigation is required.

Impact GE-14: Unique Geologic Features

Impact GE-14 **Implementation of the Project would not result in a substantial change of topography or destruction of unique geologic features. (No Impact) *[Criterion L.f]***

Most of the Project site is relatively flat, with elevations generally ranging from approximately 0 feet to 20 feet SFCD, because the site consists of fill areas or low lying shoreline areas. Maximum ground surface elevation near the Project site is on Bayview Hill (west of Candlestick Point), which reaches an elevation of approximately 400 feet SFCD. The Jamestown Avenue area of Candlestick Point is at about 75 feet in elevation. There are no unique geologic features, such as prominent hills, exceptional rock outcroppings, or similar features.

The Project would alter surface topography for new development, including about three feet of fill in some areas. The HPS Phase II shoreline would be altered with new seawalls or other shoreline protection. The Project would not substantially change site topography or affect unique geologic features, and would have no impact on such features. No mitigation is required.

Cumulative Impacts

The geographic context for the analysis of cumulative impacts resulting from geologic hazards is generally site-specific, because each Project site has a different set of geologic considerations that would be subject to specific site-development and construction standards. Soil and geologic conditions are site-specific and there is little, if any, cumulative relationship between the Project and other areas in the City. As such, the potential for cumulative impacts to occur is geographically limited for many geology and soils impact analyses; however, variations from a site-specific cumulative context are identified, where they occur.

In common with the rest of California, San Francisco is in a seismically active area and is subject to risk of damage to persons and property as a result of seismic groundshaking. Given the risk from seismic activity associated with all development in seismically active areas, this impact would be significant if it were not

[437] GTC, 2005.

mitigated by building code requirements. Building in California is strictly regulated by the CBC, as adopted and enforces by each jurisdiction, to reduce risks from seismic events to the maximum extent possible. Impacts associated with potential geologic hazards related to fault rupture would occur at individual building sites and would be related to the site's location relative to fault zones, the composition of the site's soil, and the structural strength of a particular building. The Project site is not in an Alquist-Priolo fault zone, and no known active faults cross the Project site, making hazards from fault rupture unlikely. The Hunters Point Shear Zone, which crosses the HPS Phase II site in the northwest, is considered inactive, as noted above.

Because the City uses and enforces the requirements of the CBC as part of the SFBC, new buildings and facilities in the City are required to be sited and designed in accordance with the most current geotechnical and seismic guidelines and recommendations. In addition, the Project would implement all necessary design features recommended by the site-specific geotechnical studies to reduce the risk from liquefaction, settlement, lateral spreading, expansive or corrosive soils, and landslides. With implementation of the previously noted mitigation measures and adherence to the SFBC and related plans, regulations, and design and engineering guidelines and practices, the Project would not make a cumulatively considerable contribution to any potential cumulative impact arising from fault rupture. The Project's cumulative impact would be less than significant.

Impacts associated with potential geologic hazards related to groundshaking and seismic-related ground failure would occur at individual building sites. These effects are site-specific, and impacts would not be compounded by additional development. New buildings and facilities in the City are required to be sited and designed in accordance with appropriate geotechnical and seismic guidelines and recommendations, consistent with the requirements of the SFBC. Therefore, although there is risk from seismic events inherent in all development in seismically active areas in the state of California, compliance with applicable regulations reduces this risk. The Project would comply with the SFBC, San Francisco Department of Public Works regulations, the California *Seismic Hazards Mapping Act*, and other agency specifications for new structures. These regulations have been formulated to preserve public safety. The Yosemite Slough bridge design and construction would be required to meet state and local regulations related to protecting against geologic and seismic hazards, including Caltrans *Bridge Design Specifications*, *Bridge Memo to Designers*, *Bridge Design Practice Manual*, and *Bridge Design Aids Manual*. As a result of implementation of these standards, the Project's potential impacts from geological hazards would be avoided and/or reduced a less-than-significant level.

Because the project would comply with the provisions of all applicable codes and regulations and because its building plans would conform to the most current seismic safety design guidelines, the Project would not make a cumulatively considerable contribution to any potential cumulative impacts arising out of strong seismic groundshaking, and the cumulative impact would be less than significant.

The impacts from erosion and loss of topsoil from site development and operation can be cumulative in effect within a watershed. Based on historic drainage patterns, watersheds in the Project vicinity that would form the geographic context for an analysis of erosion impacts are the Islais Creek Basin and the Yosemite Basin.[438] Development throughout the City is subject to runoff, erosion, and sedimentation prevention requirements, including the applicable provisions of Phases I and II of the NPDES permit process and

[438] San Francisco Public Utilities Commission, *Urban Watershed Planning Charrette, Bayside Basins Summary Report*, May 2008.

implementation of fugitive dust control measures in accordance with BAAQMD Rule 403. Construction activities would be required to comply with all code requirements, including surface soil erosion control. Any erosion potential would be reduced or avoided through compliance with applicable codes and mitigation measures. Because all development in the watershed would be subject to these provisions, cumulative impacts related to erosion or the loss of topsoil would not be significant.

Implementation of the Project would modify soil and topographic conditions at the site to accommodate development and provide a stable and safe physical environment. The construction phase of the Project could expose soil to erosion by wind or water. Development of other cumulative projects in the vicinity of the Project site, including the Yosemite Slough Restoration Project, could expose soil surfaces and further alter soil conditions. To minimize the potential for cumulative impacts that could cause erosion, the Project and cumulative projects in the adjacent area are required to conform to the provisions of applicable federal, state, County, and City laws and ordinances. Because the Project would be in compliance with applicable BAAQMD and NPDES permit requirements, and would implement and maintain the BMPs required by the Project's SWPPP, the Project would not make a cumulatively considerable contribution to any potential cumulative impact related to soil erosion or loss of topsoil, and the cumulative impact of the Project would be less than significant.

As with seismic groundshaking impacts, the geographic context for analysis of impacts on development from unstable soil conditions, including landslides, liquefaction, subsidence, collapse, or expansive or corrosive soils generally is site-specific. Because all development is required to undergo analysis of geological and soil conditions applicable to the specific individual project, and because restrictions on development would be applied in the event that geological or soil conditions pose a risk to safety, it is anticipated that cumulative impacts from development on soils subject to instability, subsidence, collapse, and/or expansive soil would be less than significant. Because the Project would implement the identified mitigation measures, the Project would not make a cumulatively considerable contribution to any potential cumulative impacts, and the cumulative impact of the Project would be less than significant.

Cumulative projects, depending on where they are located, could substantially change site topography and/or unique geologic or physical features at their respective sites. In certain situations this could be a potentially significant impact, particularly if a large number of cumulative projects were to change topography or unique geologic features. Nothing in the Project site circumstance or the surrounding area suggests that such a cumulative impact could occur. Most of the Project site is relatively flat, with elevations ranging from approximately 0 feet to 20 feet SFCD, because the site consists of fill areas or low lying shoreline areas. Maximum ground surface elevation near the Project site is on Bayview Hill (west of Candlestick Point), which reaches an elevation of approximately 400 feet SFCD. The Jamestown Avenue area of Candlestick Point is at about 75 feet SFCD in elevation. There are no unique geologic features, such as prominent hills, exceptional rock outcroppings, or similar features. The Project would alter surface topography for new development, including about three feet of fill in some areas. The HPS Phase II shoreline would be altered with new seawalls or other shoreline protection. Overall, the Project would not substantially change site topography or affect unique geologic features, and would have no impact on such features. Therefore, there is no cumulative impact related to topography and unique geographic features.

SECTION III.M HYDROLOGY AND WATER QUALITY

III.M.1 Introduction

This section describes the existing hydrology and water quality conditions within the Project site and vicinity and evaluates the potential for the Project to result in environmental impacts related to surface and groundwater quality, stormwater drainage, and flooding. This section discusses construction and operational impacts associated with stormwater runoff, combined sewer overflows, flood risk (including potential effects from future sea level rise and seismically induced events), marina basin dredging, and Yosemite Slough bridge construction. This section identifies both Project-level and cumulative environmental impacts, as well as feasible mitigation measures that could reduce or avoid the identified impacts. Potential water quality impacts associated with hazardous materials are discussed in Section III.K (Hazards and Hazardous Materials). Potential impacts to biological resources from water quality impacts are discussed in Section III.N (Biological Resources).

Information sources for the analysis presented in this section include contacts with public agency staff and reference documents from the State Water Resources Control Board (SWRCB), the California Department of Water Resources (DWR), the San Francisco Bay Regional Water Quality Control Board (SFRWQCB), the San Francisco Bay Conservation and Development Commission (BCDC), the Association of Bay Area Governments (ABAG), the Federal Emergency Management Agency (FEMA), the San Francisco Public Utilities Commission (SFPUC), and several City departments. Related plans and policies are discussed, including the *San Francisco Bay Basin Water Quality Control Plan* (Basin Plan),[439] the *City and County of San Francisco Stormwater Management Plan* (January 2004),[440] *San Francisco Bay Plan*,[441] the *Draft San Francisco Stormwater Design Guidelines*.[442] In addition, the Baseline Stormwater calculations conducted by PBS&J (refer to Appendix M1 [Stormwater Runoff Calculations]) and several technical reports and analyses prepared by consultants on behalf of Lennar Urban were used during the preparation of this section, and are listed as cited sources.

III.M.2 Setting

Regional Hydrology

The Bay Area climate is generally characterized as dry-summer subtropical (often referred to as Mediterranean), with cool wet winters and relatively warm dry summers. San Francisco exemplifies a particular type of Mediterranean climate that, due to the proximity of coastal waters, experiences cool, often cloudy summers. The approximate annualized average high temperature is 64 degrees Fahrenheit (ºF); the average low temperature is 51ºF. The average annual rainfall in the vicinity of the Project site, for the period between 1914 and 2008, is approximately 21.1 inches, the majority of which occurs from

[439] San Francisco Regional Water Quality Control Board, *San Francisco Bay Basin Water Quality Control Plan (Basin Plan)*, As amended, January 18, 2007. Available: http://www.swrcb.ca.gov/sanfranciscobay/basin_planning.
[440] City and County of San Francisco, *Stormwater Management Plan*, January, 2004.
[441] San Francisco Bay Conservation and Development Commission, *San Francisco Bay Plan*, June 1998.
[442] City of San Francisco, San Francisco Public Utilities Commission and Port of San Francisco, *Draft – San Francisco Stormwater Design Guidelines*, 2009.

October through April.[443] During the period of record, annual rainfall has varied from 8.7 inches (1976) to 43.8 inches (1983), with a one-day high of 5.5 inches of precipitation on November 5, 1994. Analysis of long-term precipitation records indicates that wetter and drier cycles lasting several years are common in the region. Severe, damaging rainstorms occur at a frequency of about once every three years.[444]

San Francisco Bay (Bay) borders the Project site to the north, east, and south. The amount and timing of precipitation, air temperature, tidal cycle, and wind patterns influence the Bay's freshwater inflow, salinity, currents, and suspended sediments. The Bay is subject to strong westerly winds, which exert stress on the water surface generating waves. Wind-generated waves suspend sediments creating turbid conditions and dispersing sediments throughout the Bay. Candlestick Point and HPS Phase II are located on peninsulas that extend into the Bay, (refer to Figure III.M-1 [Combined and Separate Storm Sewer System and Receiving Water Bodies]). Yosemite Slough, a tidal inlet, and South Basin, an embayment,[445] separate Candlestick Point and HPS Phase II.

The portion of the Bay east of the Project site is referred to in the San Francisco Bay Basin Water Quality Control Plan (Basin Plan) as the San Francisco Bay Lower (Lower Bay) in the South Basin Hydrologic Planning Area. Major water features along the Lower Bay shoreline in the vicinity of the Project site, from north to south, include Islais Creek Channel, India Basin, South Basin, Yosemite Slough, and Candlestick Cove (refer to Figure III.M-1). Freshwater flow into the South Basin is limited to flow from creeks and stormwater outfalls.[446] Circulation is limited because the basin's location restricts exposure to tidal action, especially when compared to other portions of the Bay. In constricted areas such as Islais Creek and Yosemite Slough, circulation is even more limited than in India Basin, South Basin, and Candlestick Cove. The San Francisco Bay Central (Central Bay) to the north has better circulation than the Lower Bay because of constant mixing of freshwater from the Sacramento/San Joaquin Delta and saltwater from the Pacific Ocean.

Watersheds and Surface Water Bodies

Project Site Watersheds

Precipitation drains as surface runoff into a network of underground and surface drainage pathways. Generally, these pathways converge into drainage culverts, streams, and/or creeks, which become progressively larger as the runoff moves downstream, eventually reaching a common discharge location. The terms "watershed" or "drainage basin" describe the area of land that drains downslope to such a location.

FIGURE III.M-1

COMBINED AND SEPARATE STORM SEWER SYSTEM AND RECEIVING WATER BODIES

Historically, small creeks near the Project site, including Yosemite Creek and Islais Creek, flowed from the east side of the City to the Lower Bay, forming the Islais Creek Basin and the Yosemite Basin.[447] However, most of the creeks in San Francisco were filled or converted to underground drains during development of the City, and as a result, there are no natural freshwater bodies or streams within the Project site.[448] Development has obscured and modified the historic drainage basin boundaries. Figure III.M-1 shows drainage basins in the Bayview Hunters Point neighborhood based on current hydrological conditions.

Islais Creek Basin

The Islais Creek Basin encompasses ten square miles,[449] and includes the northern portion of HPS Phase II. Islais Creek originates in Glen Canyon, over three miles west and slightly north of the Project site. The only remaining surface extents of the historic creek channel are in Glen Canyon and at the San Francisco Bay waterfront near the foot of Potrero Hill and Cesar Chavez Street. Flows from Islais Creek are conveyed to the combined sewer system. Surface inflow to Islais Creek Channel occurs during the rainy season from direct stormwater runoff from areas adjacent to the channel and from treated wastewater discharged from the combined sewer system (described in more detail below) through the Quint Street outfall. Four deep water combined sewer overflow (CSO) structures[450] are also located along the Islais Creek Channel.[451]

Yosemite Basin

The Yosemite Basin encompasses approximately three square miles[452] and contains the southern portion of HPS Phase II and Candlestick Point. Yosemite Creek historically originated from a hilltop spring in McLaren Park and ran through what are now the Portola and Bayview neighborhoods before discharging into San Francisco Bay via Yosemite Slough. The creek is culverted and channelized, and the channel receives direct stormwater runoff from areas adjacent to the channel and from two CSO structures with nearshore discharges.

Surface Water Bodies

Yosemite Slough

Yosemite Slough is located along the southwestern shoreline of HPS Phase II and along the northern shoreline of Candlestick Point. Historically, Yosemite Slough was part of a much broader tidal marsh and mudflat complex that served as the transition between Yosemite Creek to the west and the Bay to the east. Starting in the late 1800s, Yosemite Slough was filled for residential and industrial use, raising the ground surface to a level approximately 5 to 20 feet above sea level. Filling of the tidelands continued through the

[452] San Francisco Redevelopment Agency and San Francisco Planning Department, *Bayview Hunters Point Redevelopment Projects and Rezoning Draft Environmental Impact Report*, October 19, 2004. File No. 1996.546E, p. III.M-3.

1960s, until the approximate current shoreline became established in 1972.[453] As noted above, surface inflow into the remnant channel of Yosemite Slough occurs during the rainy season from treated wastewater discharged from the combined sewer system through three nearshore CSO structures and from direct stormwater runoff from areas adjacent to the slough. A planned restoration of Yosemite Slough includes restoring 12 acres of upland fill back to tidally influenced wetlands. The restoration project is being implemented by the California State Parks Foundation in collaboration with local environmental groups.

South Basin

South Basin is located along the southern shoreline of HPS Phase II and the eastern shoreline of Candlestick Point. The South Basin is an embayment with direct and open tidal exchange with the Lower Bay. Yosemite Slough flows into South Basin from the west, and South Basin also receives stormwater discharges from separate drainage systems located in HPS Phase II and Candlestick Point.[454]

Candlestick Cove

Candlestick Cove is located along the southern shoreline of Candlestick Point. Historically, there were two small creeks flowing from the adjacent uplands to the Lower Bay in this vicinity; however, both creeks have been filled. This portion of the Lower Bay receives surface drainage from one nearshore CSO structure and from direct stormwater runoff and discharge from a separate storm sewer outfall.[455]

Groundwater Basins

Groundwater basins in the vicinity of the Project site, as defined in the Basin Plan, include (from north to south) Islais Valley (Basin ID: 2-33; area: 9.2 square miles), South San Francisco (Basin ID: 2-37; area: 3.4 square miles), and Visitacion Valley (Basin ID: 2-32 area: 9 square miles).[456] Hydrologic regions and basin identification numbers are designated by DWR.

Sources of recharge into the groundwater basins include infiltration of rainfall, landscape irrigation, and leakage from water, wastewater, and storm drain pipes. A study performed in 1993, found that the average groundwater recharge for the water years 1987 to 1988 was 1,836 acre-feet per year in Islais Valley, 696 acre-feet per year in South San Francisco, and 269 acre-feet per year in the Visitacion Valley groundwater basin.[457] Generally, the basins in the Project site, which are not used for water supply, have maintained stable groundwater levels.[458]

Stormwater Drainage

Combined Sewer System

Facilities and Operation

Most stormwater runoff in the City is collected via a combined sewer system managed by the SFPUC. This system combines stormwater runoff and wastewater flows in the same network of pipes, conveying flows to facilities where they are treated prior to discharge to the Lower Bay or Pacific Ocean through outfall structures along the shoreline. Discharges from the combined sewer system are regulated under two individual National Pollutant Discharge Elimination System (NPDES) permits (waste discharge requirements [WDRs]) issued by the SFRWQCB. The Project site discharges to east side facilities that discharge to the Lower Bay. The applicable NPDES Permit/WDR is discussed in the Regulatory Setting section.

The combined sewer system is designed to ensure that most wastewater receives secondary treatment (removal of settleable materials and partial removal of dissolved materials). During dry weather, wastewater and any dry-weather runoff (e.g., from irrigation runoff, discharge from underground springs, or pipe leaks) from the eastern portions of the City is conveyed to the Southeast Water Pollution Control Plant (SWPCP), at Phelps Street between Jerrold and Evans Avenues, just northwest of the Project site (refer to Figure III.M-2 [Existing SFPUC Major Water Quality Features]). The SWPCP treats approximately 67 million gallons per day (MGD) during dry weather (approximately 80 percent of the City's total wastewater flow)[459] and has the capacity to treat 150 MGD to a secondary treatment standard. Secondary treatment uses pure oxygen to encourage growth of microorganisms that consume organic material and improve the purity of the wastewater. Wastewater is then put into a second round of settling tanks where the microorganisms are separated from the cleaned water, and disinfected. Treated, dechlorinated wastewater is then discharged through the Southeast Plant deep water outfall at Pier 80.

If the combined wet-weather flows exceed 150 MGD, the plant can also treat an additional 100 MGD to a primary treatment standard (removal of settleable materials) plus subsequent disinfection and dechlorination.[460] Wet weather flows that are treated to the primary standard (plus disinfection) are only discharged from the Southeast Pollution Control Outfall (Pier 80 outfall), while flows treated to the secondary standard and disinfected are discharged through the Quint Street outfall to the Islais Creek Channel when maximum capacity of the plant is reached.

During larger storm events, excess flows that cannot be treated at the SWPCP are treated and discharged through the Bayside Wet Weather Facilities (BWWF), which consist of a series of interconnected underground tanks, tunnels, and outfall structures. During dry weather, the BWWFs transport combined wastewater to the SWPCP. During wet weather, the underground transport tunnels provide a total storage capacity of approximately 193 million gallons, while pumps continue to transfer combined wastewater and stormwater to the SWPCP. The BWWFs were designed, in accordance with the NPDES permit, to capture

EXISTING SFPUC MAJOR WATER QUALITY FEATURES

FIGURE III.M-2

and store sufficient volumes of sewage and stormwater to limit discharges from the BWWF to specified long-term average numbers of annual discharges (CSOs). The Project site discharges to the system that was designed to achieve a long-term annual average of ten, eight, four, or one CSO events, depending upon location. When the treatment capacity of the SWPCP is fully maximized, the wet weather facilities retain storm flows for later treatment. The tanks allow floatable and settleable solid materials to be removed, similar to primary treatment processes. The materials retained in the storage and transport boxes are flushed to the treatment plants after storms. This level of treatment meets the minimum treatment specified by the US Environmental Protection Agency (USEPA) Combined Sewer Overflow Control Policy (CSO Policy) I50 FR 18688; April 11, 1994.

During very large storm events that cause flow to the SWPCP to exceed 110 MGD, and when the treatment and storage capacities of the combined system are exceeded, excess flows receive "flow-through treatment," similar to primary treatment, to remove settleable solids and floatable materials and flows are then discharged into the Lower Bay through any one of 29 CSO structures located along the City's Bayside waterfront from Fisherman's Wharf to Candlestick Point. The volume of a CSO discharge is a function of the storm intensity, storm duration, treatment rate, and available storage. CSO discharges typically consist of about 6 percent sewage and 94 percent stormwater.[461] All solids that settle out in the storage/transport structures are flushed to the SWPCP after the rainstorm. There are six CSO structures in the vicinity of the Project site, in Yosemite Slough/South Basin and Candlestick Cove (CSO-37 through CSO-43 as depicted on Figure III.M-2).

At Candlestick Point, the Candlestick Park stadium and Alice Griffith public housing site discharge stormwater runoff to the combined sewer system, while the Candlestick Point State Recreation Area (CPSRA) and portions of the stadium parking lots have separate storm sewer systems (refer to description below). Stormwater at HPS Phase II does not flow to the City's combined sewer system, but is discharged to the Bay via separate stormwater system outfalls and overland flows (refer to description below).

Current Combined Sewer System Planning Efforts

The SFPUC is preparing a long-term strategy for the management of the City's wastewater and stormwater, to be presented in a Sewer System Master Plan.[462] The Sewer System Master Plan will examine the capacity, condition, and long-term management strategies for the City's combined sewer system infrastructure and facilities.

As part of the long-term planning process, the SFPUC is examining alternative discharge options for treated combined sewer flows. In 2006, the SFPUC updated the Recycled Water Master Plan (described in the Regulatory Framework), to develop a terrestrial discharge option for treated wastewater for landscaping purposes. The Recycled Water Master Plan identifies where and how San Francisco could most feasibly develop recycled water in the City and provides a strategy for implementing the recycled water projects.[463]

Separate Storm Sewer Systems

Approximately ten percent of the City is served by separate storm sewer systems or is lacking storm sewer infrastructure. Existing separate storm sewer systems do not generally provide treatment prior to discharge to the Lower Bay.[464] Similarly, in areas lacking storm sewer infrastructure, untreated surface runoff drains directly to the Bay.[465] The separate storm sewer systems are regulated under the NPDES, also discussed in the Regulatory Framework.

The portions of the Project site that have a separate storm sewer system are shown in Figure III.M-1. Approximately 47 acres surrounding the Candlestick Park stadium discharge to a separate storm sewer system.[466] The San Francisco Recreation and Park Department maintains the storm drain system for this area, including catch basins, piping, pump stations, and outfalls, and the SFPUC provides assistance on outfall maintenance. This storm sewer system is more than 30 years old, and historic flooding has occurred because of the inadequate capacity of the system.[467] Approximately 120.2 acres of the 154-acre Candlestick Park State Recreation Area (CPSRA) are within the Project site and are served by a separate storm sewer system, managed under the jurisdiction of the California Department of Parks and Recreation.[468]

HPS Phase II had a combined sewer system in the 1940s; however, the Navy implemented a series of projects in 1958, 1973, and 1976 to separate the wastewater and storm sewer systems. Most of HPS Phase II is served by the separate storm sewer system; however, areas along the shoreline drain directly to the Lower Bay via overland flow and subsurface migration of infiltrated water.[469] The Navy has obtained Waste Discharge Identification Number (241S011455) for HPS Phase II stormwater discharge under the Industrial General Permit (discussed in the Regulatory Framework). In accordance with this permit, HPS Phase II stormwater is discharged to San Francisco Bay through 33 storm water outfalls along the perimeter of HPS Phase II. HPS Phase II wastewater is conveyed to the SWPCP through a force main at Crisp Road.

Flood Protection

Flood management within the Project site is the responsibility of CPSRA and property owners (for Candlestick Point) and the Navy (for the HPS Phase II), who are responsible for the development and maintenance of flood protection facilities. The flood protection facilities primarily consist of stormwater collection systems and coastal protection features, including sea walls and various forms of shoreline armoring (such as rock rip-rap).

Dam Failure Inundation Risk

The Project site is not within a mapped dam failure inundation area (refer to Figure III.M-3 [Dam Failure Inundation Areas in the Project Vicinity]). However, an area adjacent to the Project site, between Yosemite Slough and US-101, has been mapped as a dam failure inundation zone for the University Mound Reservoir.

---

[464] It should be noted, however, that proposed separate sewer systems at the Project site would include treatment mechanisms and BMPs.

[469] City and County of San Francisco Planning Department and San Francisco Redevelopment Agency, *Hunters Point Shipyard Reuse Final Environmental Impact Report*, certified February 8, 2000. File No. 1994.061E.

Existing Flood Risk

The Federal Emergency Management Agency (FEMA) implements the National Flood Insurance Program (NFIP) under its Flood Insurance Administration, which prepares Flood Insurance Rate Maps (FIRMs) that identify areas subject to flood inundation, most often from a flood having a one percent chance of occurrence in a given year (also known as a "base flood" or "100-year flood"). FEMA refers to the portion of the floodplain or coastal area that is at risk from a flood of this magnitude as a Special Flood Hazard Area (SFHA). For SFHAs, FIRMs may specify the anticipated water surface elevation during the base flood, or Base Flood Elevation. When a Base Flood Elevation has not been formally established for a SFHA, the Base Flood Elevation may be estimated by a qualified engineer. In coastal areas, the Base Flood Elevation may be the equivalent of the height of tidal waters during an extreme high tide event, coupled with flooding from a large storm.

No FIRMs have been formally published by FEMA for the City; thus, the Base Flood Elevation for a 100-year flood event has not been formally established. However, on September 21, 2007, FEMA issued a preliminary FIRM for San Francisco, which tentatively identified SFHAs along the City's shoreline, including portions of the Project site.

Until finalization of the FIRMs, Interim Floodplain Maps have been prepared under the City's Floodplain Management Program to delineate SFHAs subject to the City's floodplain development requirements (see Regulatory section for details). The floodplain management regulations in this ordinance are consistent with the NFIP requirements for communities like San Francisco, where FEMA is in the process of preparing, but has not completed a final FIRM.

As shown on Figure III.M-4 (Preliminary 100-Year Flood Zones within and Adjacent to the Project), portions of Candlestick Point and HPS Phase II are within or adjacent to the following mapped 100-year flood hazard areas on the preliminary FIRM:

- Zone A: Areas with a one percent annual chance of flooding; no Base Flood Elevations determined
- Zone V: Coastal areas with a 1 percent or greater chance of flooding and an additional hazard associated with storm waves; no Base Flood Elevations determined[470]

Within the Project site, tidal flooding of the HPS Phase II storm drain system has been identified during high tides in low-lying areas throughout HPS Phase II. In addition, tidal flooding has also been identified within the storm drain system at Candlestick Point.

The extent of the Zone A SFHAs shown for the Project site on the preliminary FIRM and the City's Interim Floodplain Maps is essentially the same.[471] However, the City has submitted comments to FEMA on the preliminary FIRM requesting revision of the Zone V (coastal flooding area) SFHA designation.

[470] NFIP regulations require coastal communities to ensure that buildings built in Zone V are anchored to resist wind and water loads acting simultaneously. Buildings in Zone V are subject to a greater hazard than buildings built in other types of floodplains. Not only do they have to be elevated above the Base Flood Elevation, they must be protected from the impact of waves, hurricane-force winds and erosion.

FIGURE III.M-4

PRELIMINARY 100-YEAR FLOOD ZONES WITHIN AND ADJACENT TO THE PROJECT

After reviewing comments and appeals related to the preliminary FIRM, FEMA will finalize the FIRMs and publish them for flood insurance and floodplain management purposes. If final FIRMs are published prior to development of the Project, development within designated SFHAs would be subject to applicable FEMA floodplain development regulations (as described in the Regulatory Framework).

Existing Shoreline Conditions

Based on a 2009 shoreline evaluation by Moffatt and Nichol, the shoreline along the Project site consists of armored embankments (riprap of concrete debris, unprotected embankments, bulkheads, pile-supported wharves, and seawalls.[472] There are two low-lying areas along the shoreline at HPS Phase II and Candlestick Point that have been preliminarily mapped by the City Administrator and FEMA as Zone A SFHAs. The shoreline evaluation determined that the shorelines adjacent to these areas need improvement because wave-induced run-up could result in coastal flooding unless the condition or elevation of the existing shoreline protection features along these areas is improved.

Extreme High Tide, Tsunamis, Seiches and Mudflows

Because of the proximity of the Project site to San Francisco Bay, coastal flooding hazards, including tsunamis, seiches, and extreme high tides could occur. The range of tides within the Bay is variable, and the Army Corps of Engineers (USACE) has developed tidal stage (i.e., height) and frequency relationships from long-term tidal measurements to estimate extreme high tide conditions within San Francisco Bay.

The estimated 100-year high tide at the Hunters Point tidal gauge (the closest gauge to both HPS Phase II and Candlestick Point) is +6.7 feet based on the National Geodetic Vertical Datum (NGVD29),[473,474] equivalent to -1.77 feet based on the San Francisco City Datum (SFCD).[475]

In addition to storm-related flooding and extreme high tides, the Project site could potentially be affected by tsunamis. Tsunamis are waves caused by earthquakes that disturb the ocean floor or by large submarine landslides. The potential hazard related to tsunamis in San Francisco Bay has been analyzed in regional studies. The expected 100-year tsunami wave run-up height at South Basin (which is adjacent to both Candlestick Point and HPS Phase II) is +4.8 feet NGVD29 (-3.8 feet SFCD).[476]

A seiche is an oscillation of a body of water. Seiches occur most frequently in enclosed or semi-enclosed basins, such as lakes, bays, or harbors, and may be triggered by strong winds, changes in atmospheric pressure, earthquakes, tsunamis, or tides. Triggering forces that set off a seiche are most effective if they operate at

[473] Ibid.

[474] NGVD29 is roughly equivalent to mean sea level.

[475] Conversion among mean sea level, NGVD29, and NAVD88 were conducted using the National Oceanic and Atmospheric Administration Vertical Datums Transformation Tool v. 2.2.4, last modified July 13, 2009, website: http://vdatum.noaa.gov/. San Francisco City Datum (SFCD) is a local vertical geodetic reference elevation established by the City Engineer for the City and County of San Francisco. SFCD = NAVD88 + 11.17 feet or NGVD29 + 8.48 feet.

[476] Garcia, A.W. and Houston, J.R., 1975. *Type 16 Flood Insurance Study: Tsunami Predictions for Monterey and San Francisco Bays and Puget Sound*, United States Army Corps of Engineers Technical Report H-75-17. Figure 58. Elevations in the Corps study are referenced to mean sea level and have been converted to NGVD29 and SFCD.

specific frequencies relative to the size of an enclosed basin. Coastal measurements of sea level often show seiches with amplitudes of a few centimeters and periods of a few minutes, caused by oscillations of the local harbor, estuary, or bay, superimposed on the normal tidal changes. Tidal records for San Francisco Bay have been maintained for over 100 years, and during this period, a damaging seiche has not occurred. A seiche of approximately four inches occurred during the 1906 earthquake, an event of magnitude 8.3 on the Richter scale. It is probable an earthquake similar to the 1906 event would be the largest experienced in the Bay Area;[477] consequently a seiche larger than four inches is considered unlikely to occur.

A mudflow is a type of landslide that occurs when runoff saturates the ground. Soil that is dry during dry weather turns into a viscous solution that slides downhill. Mudflows typically cause more damage than clear-water flooding because debris-filled water moves with greater force. Refer to Section III.L (Geology and Soils), Impact GE-6 through Impact GE-8, for a discussion of the potential for landslides to occur at the Project site.

Future Flood Risks

The current potential for coastal flooding will likely be exacerbated in the foreseeable future because of rising sea levels. Globally, sea level has been rising for the past 10,000 years as the result of the end of the last glacial epoch.[478] The global rate of sea level rise had been relatively consistent over the last 5,000 years, at approximately 0.0039 foot/year.[479] However, the current average rate of sea level rise for the San Francisco Bay area is 0.0066 foot/year at the San Francisco tide station.[480] The difference between the rate of sea level rise measured in the Bay Area and the rate of global sea level rise can be accounted for by local changes in ground surface elevation, such as tectonic uplift or subsidence. The rate of relative sea level change is variable even on a local scale.[481]

There is also evidence that sea level rise is accelerating. The cause of the measured acceleration in the rate of sea level rise is primarily attributed to ocean warming (thermal expansion), continental ice melt, and land elevation changes.[482,483,484] The most common explanation for the increased rate of sea level rise is an increase in global

temperatures associated with emission of greenhouse gases.[485] Section III.S (Greenhouse Gas Emissions) contains a discussion of the relationship between greenhouse gas emissions and climate change effects.

State and federal regulatory agencies review a range of possible scenarios when evaluating the potential risks and costs of sea level rise for future development projects. For planning purposes, the USACE evaluates three scenarios of sea level rise; low risk, assuming the current rate of sea level rise, or 19.7 inches (0.5 meter) by 2100; moderate risk, assuming a sea level rise of 39.4 inches (1.0 meter) by 2100; and, high risk, assuming a sea level rise of 59.0 inches (1.5 meters) by 2100.[486] California Executive Order S-13-08 (November 14, 2008) states that all state agencies planning construction projects in areas vulnerable to future sea level rise shall consider a range of sea level rise scenarios for the years 2050 and 2100 to assess project vulnerability, and, to the extent feasible, reduce expected risks and increase resiliency to sea level rise. This Executive Order also directs the California Resources Agency, in cooperation with the Department of Water Resources and the California Energy Commission, to prepare a Sea Level Rise Assessment Report by December 1, 2010 to advise how California should plan for future sea level rise. The Governor of California's Delta Vision Blue Ribbon Task Force has adopted a sea level rise of 55 inches by 2100 for planning purposes, until issuance of an Executive Order determining otherwise.[487] The San Francisco Bay Conservation and Development Commission (BCDC) has prepared maps for areas inundated by 16 inches of sea level rise by 2050 and 55 inches of sea level rise by 2100.[488] Therefore, extrapolating BCDC projections to the 2075 mid-point, sea level rise would be about 36 inches (3 feet), although some studies have concluded this rise would not occur until after the year 2100.[489]

Sea level rise presents an important issue in the planning of development and hazard analysis in coastal areas.[490] Within the Project site, this includes the potential for increased risk of flooding because of higher sea surface levels. A determination or conservative estimate of the potential magnitude of future sea level rise is needed to assess potential impacts related to sea level rise and to identify mitigation measures found to be appropriate to address the impact(s)[491,492] and is provided in the analysis.

Although FEMA has not formally defined the Base Flood Elevations for the Project site, Moffatt and Nichol[493] has evaluated extreme high tide water level elevations for the Project site using NOAA tide gauge data. The Moffatt and Nichol study estimates that development at the Project site constructed at a level less than +6.7

feet NGVD29 (-1.8 feet SFCD), could be susceptible to flooding associated with the 100-year extreme high tide event. However, as sea level rises, coastal flood hazards associated with storm-related flooding, extreme high tides, and/or tsunamis adjacent to or affecting the Project site would increase. Assuming a 36-inch rise in sea level by 2075, the future base flood (100-year event) elevation would be +9.7 feet NGVD29 (+1.2 feet SFCD).[494] Projected inundation zones for the future Base Flood Elevation, given a 36-inch increase in sea level, are shown in Figure III.M-5 (Flood Zones [Existing and with a 36-Inch Sea Level Rise]). This figure reflects the proposed condition without fill and without shoreline improvements.

Water Quality

Impaired Water Bodies and Total Maximum Daily Loads

The Lower Bay has been identified as an impaired water body by the SWRCB in compliance with *Clean Water Act of 1977* (CWA) Section 303(d), because it does not meet the water quality objectives of the Basin Plan, California Toxics Rule (CTR), or National Toxics Rule (NTR) for listed beneficial uses (industrial service supply; ocean, commercial and sport fishing; shellfish harvesting; estuarine habitat; fish migration; preservation of rare and endangered species; fish spawning; wildlife habitat; water contact recreation; non-contact water recreation; and navigation). The pollutants that have been identified as causing impairment in the Lower Bay are chlordane, dichloro-diphenyl-trichloroethane (DDT), dieldrin, dioxin compounds, exotic species, furan compounds, mercury, and polychlorinated biphenyls (PCBs).[495] Islais Creek, north of the Project site, is listed as an impaired water body because of ammonia, chlordane, dieldrin, hydrogen sulfide, polynuclear aromatic hydrocarbons (PAHs), and sediment toxicity. Candlestick Cove is listed as an impaired water body for indicator bacteria. The potential sources of pollutants identified in the impaired water bodies adjacent to the Project site include non-point sources,[496] CSOs, industrial and municipal point sources,[497] atmospheric deposition, ballast water,[498] resource extraction, natural sources, and unknown sources. A Total Maximum Daily Load (TMDL)[499] for the entire San Francisco Bay has been developed for mercury and has been incorporated by amendment into the Basin Plan. A TMDL for the entire San Francisco Bay has also been developed for PCBs, and its adoption is pending approval by the SWRCB and the USEPA.

---

494 Ibid.

495 USEPA, 2007. 2006 CWA Section 303(d) List of Water Quality Limited Segments, June 28, 2007.

496 Non-point sources are diffuse sources of pollutants, generated over a large area, and not discharged at a discrete location, such as runoff from a natural watershed.

497 Point sources are pollutant sources discharged at a discrete location, such as a wastewater treatment plant outfall.

498 Water used to weight a ship to the water's surface, preventing toppling during heavy winds.

499 On a broad level, the TMDL process leads to a "pollution budget" designed to restore the health of a polluted body of water. The TMDL process provides a quantitative assessment of water quality problems, contributing sources of pollution, and the pollutant load reductions or control actions needed to restore and protect the beneficial uses of an individual waterbody impaired from loading of a particular pollutant. More specifically, a TMDL is defined as the sum of the individual waste load allocations for point sources, load allocations for non-point sources, and natural background such that the capacity of the water body to assimilate pollutant loading (the loading capacity) is not exceeded (40 CFR Section 130.2). In other words, a TMDL is a calculation of the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards which will ensure the protection of beneficial uses.

FLOOD ZONE (EXISTING AND WITH A 36-INCH SEA LEVEL RISE)

Regional Monitoring Program

The quality of surface water and groundwater in the vicinity of the Project site is affected by past and current land uses at the site. Water quality within the watershed is also affected by the composition of local geologic materials. In 1993, the San Francisco Estuary Institute initiated the Regional Monitoring Program (RMP) for the San Francisco Bay for the general purposes of assessing regional water quality conditions and characterizing patterns and trends of contaminant concentrations and distribution in water and sediment, as well as identifying general sources of contamination to the Bay. The program has established a database of water quality and sediment quality in the estuary, particularly with regard to toxic and potentially toxic trace elements and organic contaminants. However, there are no water quality RMP monitoring stations (fixed locations or random sites) in close proximity to the Project site;[500] therefore, the trends identified by this monitoring program reflect regional, rather than site-specific, water quality conditions. Based on monitoring results from the RMP for 2002 to 2006, water column samples collected from the Lower Bay did not contain contaminant concentrations above regulatory thresholds as listed in Table III.M-1 (Lower Bay Regulatory Thresholds).[501] A TMDL is in effect for mercury for the entire San Francisco Bay.

Table III.M-1 Lower Bay Regulatory Thresholds

Compound	*Units*[a]	*4-day Average*	*1-hour Average*	*24-hour Average*
Dissolved Arsenic	µg/L	36	69	NA

Occurrence of CSO Events

In accordance with the Long-Term Control Plan required under the City's NPDES Wastewater Discharge Permit (see Regulatory Framework, below) SFPUC designed its combined sewer system based on historical rainfall to achieve the long-term average goal of only one CSO event per year along the southeast sector of the City. This wet weather performance criteria (no more than one CSO per year) is a long-term average and is not to be used to determine compliance or non-compliance with the wastewater operations NPDES permit/WDR because some years are wetter than others and may contribute more flow to the treatment system than anticipated and designed.[502] However, the SFPUC is also required to optimize the operation of its system to minimize overflows and maximize pollutant removal. No CSO events are untreated because all discharges receive at least primary treatment in the storage and transport system.[503]

[502] The California Regional Water Quality Control Board, San Francisco Bay Region recognizes that some years are wetter than others and may contribute more flow than anticipated in the system design criteria.

[503] California Regional Water Quality Control Board, San Francisco Bay Region. 2008, Order No. R2-2008-0007 and NPDES No. CA0037664, Waste Discharge Requirements for the City and County of San Francisco Southeast Water Pollution Control Plant, North Point Wet Weather Facility, and Bayside Wet Weather Facilities and Wastewater Collection System, adopted January 30, 2008.

The principal pollutants in CSOs are pathogens, oxygen depleting substances, TSS, toxics (metals, petroleum hydrocarbons, man-made organic chemicals), nutrients, and floatables. CSOs can adversely affect some beneficial uses of the Lower Bay such as aquatic life support, fish consumption, shellfish harvesting, and recreation. On the 303(d) list, CSOs are listed as a source of pollutants causing impairment in Islais Creek. Wet weather beach water quality data collected by the SFPUC and San Francisco Department of Public Health (DPH) in the vicinity of the Project, which includes the effects of CSOs, discharges from separate storm drain systems, and runoff discharging directly into the Bay, indicate levels above those presented in the Basin Plan water quality objective for total coliform bacteria. Also, the other pathogen indicators that are monitored have significantly higher concentrations in wet weather than in dry weather.

Beach Water Quality

The SFPUC and the DPH collaboratively implement a shoreline beach water quality monitoring program. The monitoring program consists of year-round weekly sampling at 14 locations around the perimeter of San Francisco where water contact recreation may occur (including three stations near the Project site). Additional monitoring is conducted whenever CSO events occur that could affect a monitored beach. Samples are analyzed at the SFPUC Microbiology Laboratory for pathogen indicator bacteria[504] that include total coliform, Escherichia coli, and enterococcus bacteria.

Adjacent to the Project site are the sampling locations at Jack Rabbit Beach, Windsurfer Circle, and Sunnydale Cove. The Windsurfer Circle and Sunnydale Cove sampling locations are nearest to CSO 043 (Candlestick Cove) and the Jack Rabbit Beach sampling location is south of CSO 042 (South Basin), as shown on Figure III.M-1 and Figure III.M-2.

Water quality in the vicinity of the three beach water quality locations is affected by both separate sewer system discharges and combined sewer discharges. Jack Rabbit Beach has the lowest pathogen indicator concentrations for both wet- and dry-weather conditions, and Windsurfer Circle has the highest concentrations. Pathogen indicator concentrations are significantly higher in wet-weather than in dry-weather for all stations. Twenty wet-weather samples exceeded the Basin Plan single sample objective for total coliforms (10,000 Most Probable Number [MPN] per 100 milliliters) at Sunnydale Cove; 40 wet-weather samples exceeded this objective at Windsurfer Circle; and, no wet-weather samples exceeded this objective at Jack Rabbit Beach. Thirteen dry weather samples exceeded the single sample objective for total coliforms at Windsurfer Circle; two dry weather samples exceeded this objective at Jack Rabbit Beach; and, no dry weather samples exceeded this objective at Sunnydale Cove. The data summary for the three locations in the vicinity of the Project site is provided in Appendix M2 (Water Quality Data Analysis). Because the beach water quality samples were collected within the Bay, the data do not indicate any violations of wastewater discharge permit conditions (the wastewater discharge permit regulates the discharge of treated combined sewer flows into the Bay).

Stormwater Discharge Quality

As runoff water flows over the landscape, it picks up dissolved chemicals, particulate material, and gross debris from the surface it flows over, prior to discharge into a water body. The effects of this runoff water

[504] Although they are not generally harmful themselves, pathogen indicators indicate the possible presence of disease-causing bacteria, viruses, and protozoa.

on surface water quality depend upon the amount and type of material being picked up and transported, as well as the amount of water or flow rate in the receiving water. Constituents and concentrations within runoff water vary according to land cover, land use, topography, and the amount of impervious cover, as well as the intensity and frequency of irrigation or rainfall. Runoff from undeveloped areas will reflect the natural chemistry and ecology of the watershed. Runoff in developed areas may typically contain oil, grease, and metals accumulated in streets, driveways, parking lots, and rooftops, as well as pesticides, herbicides, particulate matter, nutrients, animal waste, and other oxygen-demanding substances from landscaped areas. Runoff from open space areas and parks may typically contain nutrients, pesticides, organic debris, bacteria, sediment, and others.

Candlestick Point

Site-specific data on stormwater runoff quality from Candlestick Point are not available. However, stormwater runoff quality is highly dependent on the natural and human-influenced nature of the drainage area. As such, stormwater runoff from urban land uses, like the current land uses at Candlestick Point, would likely contain pathogens, metals, nutrients, sediment, trash and debris, oxygen-demanding substances, various organic chemicals, pesticides, PCBs, and mercury.

Hunters Point Shipyard Phase II

The stormwater runoff from HPS Phase II is currently permitted under the General NPDES Permit for Stormwater Discharges Associated with Industrial Activities (Industrial General Permit) (Water Quality Order 97-03-DWQ; General Permit No. CAS000001). Water quality monitoring is performed according to terms specified in the Industrial General Permit (see Regulatory Framework), which requires sampling of stormwater runoff from all outfalls that produce a discharge and analysis of basic indicator parameters. By comparing USEPA stormwater quality benchmarks[505] to the stormwater monitoring data from the HPS Phase II site, the extent to which stormwater pollutant concentrations are elevated above those benchmarks can be identified. Indicator parameters exceeding the benchmarks do not necessarily constitute a violation of water quality standards or an exceedance of permit conditions. Parameter benchmarks are designed to indicate a potential problem and to measure if existing BMPs are effective.

[505] The Draft Final 2005 Industrial General Permit contains parameter benchmark concentrations for certain constituents that are derived from USEPA's Multi-Sector General Permit (MSGP). The benchmarks will take effect when the Draft Final Permit is adopted. The benchmarks are not numeric discharge limits, but are used to assess if site Best Management Practices (BMPs) are effective for reducing concentrations of pollutants of concern. The Draft Permit requires that if runoff concentrations are above one or more benchmarks, the discharger must revise its Storm Water Pollution Prevention Plan (SWPPP) to include more effective BMPs, and collect samples from the next two consecutive qualifying storms.

Six annual reports for stormwater discharges at HPS Phase II representing the 2002/03 through 2007/08 reporting periods were available at the SFRWQCB for review.[506,507,508,509,510,511] With the exception of the Annual Report for the 2007-2008 reporting period, separate reports were prepared for the inactive industrial landfill and the remainder of HPS Phase II. Landfill monitoring data were available in Annual Reports for the 2004/05, 2006/07, and 2007/08 reporting periods. Summaries of the data contained in these reports are included in Appendix M2. The basic indicator parameters are as follows:

pH. pH is a numeric measurement of the hydrogen-ion concentration in water. The neutral range is usually considered to be within 6.5 to 8.5. At values less than 6.5, the water is considered acidic; above 8.5 it is considered alkaline or basic. Pure rainfall tends to have a pH of a little less than 7. Many industrial facilities handle materials that can affect pH. pH is not listed on the 303(d) list as impairing water quality in the Lower Bay.

Specific Conductance (SC). SC is a numerical expression of the ability of water to carry an electric current. It provides an indication of the degree of mineralization, salinity, or the total dissolved solids present (TDS) in stormwater discharges. Rainwater has a SC of close to zero and seawater has a very high SC. High SC could affect the usability of waters for drinking, irrigation, and other commercial or industrial use. SC is not listed on the 303(d) list as impairing water quality in the Lower Bay.

Total Suspended Solids (TSS). TSS is an indicator of the undissolved solids in stormwater runoff. Sources of TSS include sediment from erosion and dirt from impervious areas, as well as other particulates. Because many pollutants can adhere to sediment particles, reducing sediment can reduce the amount of these pollutants in stormwater discharges. TSS is not listed on the 303(d) list as impairing water quality in the Lower Bay.

Total Organic Carbon (TOC). TOC is an indicator of the total organic matter present in water. Organic matter can be natural (such as from plants and animals) or man-made (synthetic organics such as fuels and pesticides). Natural organic matter can deplete the receiving waters of oxygen as it biodegrades. Synthetic organics, even when discharged at low concentrations, can be harmful to and, in some cases, bioaccumulate in aquatic life. TOC is not listed on the 303(d) list as impairing water quality in the Lower Bay.

[511] Department of the Navy Base Realignment and Closure Program Management Office West, *2007/2008 Annual Report for Storm Water Discharges Associated with Industrial Activities, Hunters Point Shipyard, San Francisco, California*, June 2008. Prepared by Marrs Services, Inc. and MACTEC Engineering & Consulting, Inc.

Oil and Grease (O&G). At very low concentrations, O&G can cause sheen on the surface of water. O&G can adversely affect aquatic life, create unsightly floating material, and make water undrinkable. Sources of O&G at industrial facilities include maintenance shops, vehicles, machines, and roads. O&G is not listed on the 303(d) list as impairing water quality in the Lower Bay.

Metals. Emissions from automobiles and many artificial surfaces of the urban environment (e.g., those covered with galvanized metal, paint, or preserved wood), contain metals, which enter stormwater as the surfaces corrode, flake, dissolve, decay, or leach. Metals are often associated with sediments in stormwater. Metals are of concern because they are toxic to aquatic organisms and can bioaccumulate (accumulate to toxic levels in aquatic animals such as fish, which can be a health hazard if consumed by other aquatic organisms or people). Metals are listed on the 303(d) list as impairing the water quality of the Lower Bay. Mercury in particular is a pollutant of concern in the Lower Bay and is the focus of a TMDL. Sources of mercury in urban runoff include mercury-containing instruments, switches and thermostats, and fluorescent lighting.[512]

In addition to the basic indicator parameters described above, certain industrial facilities, as determined by the facility's Standard Industrial Classification (SIC), must analyze stormwater runoff samples for additional parameters. HPS Phase II contains many parcels that are leased to other entities; therefore, the additional parameters monitored at each outfall depend on the SIC(s) of the facilities discharging to the outfall. The additional parameters generally include heavy metals, such as copper and zinc. In addition, runoff from the industrial landfill portion of HPS Phase II is monitored for additional parameters that could potentially be present at the landfill, in accordance with the facility's Storm Water Discharge Management Plan; additional constituents analyzed in runoff from the industrial landfill include semi-volatile organic compounds, PCBs, and metals.

At each outfall, there was at least one parameter whose mean concentration exceeded the benchmark. Parameter benchmarks were exceeded for conductivity, total suspended solids (TSS), total copper, total zinc, and total lead; benchmarks for conductivity and TSS were exceeded most frequently.

Sediment Quality

Regional sediment sampling is being conducted by the San Francisco Estuary Institute as part of the RMP. The sampling occurs throughout the Bay, and a few samples have been taken near the Project site. Elevated levels of methylmercury, PCBs, and PAHs were identified in nearshore sediments samples taken near the Project site.[513] The SFRWQCB also conducted and/or reviewed sediment quality data as part of the Bay Protection and Toxic Cleanup Plan for sites throughout the Bay.[514] Lower Islais Creek was listed as a toxic

[513] San Francisco Estuary Institute (SFEI), 2007, *The Pulse of the Estuary: Monitoring and Managing Water Quality in the San Francisco Estuary. SFEI Contribution 532.* San Francisco Estuary Institute, Oakland, CA, pp. 34, 39, 42.
[514] State Water Resources Control Board (SWRCB), *Consolidated Toxic Hot Spots Cleanup Plan*, June 1999.

hot spot[515] because of sediment contamination and impacts to aquatic life; the constituents of concern included PCBs, chlordane, dieldrin, endosulfan, hydrogen sulfide, ammonia, and PAHs. The SFRWQCB indicates the most likely source of pollutants is stormwater entering the channel directly or through the CSOs. Another possible source is the SWPCP outfall at Quint Street. However, because of recent improvements in the treatment of discharges from the CSOs and the Quint Street outfall, historic discharges from these sources may have had a more significant impact than current discharges.[516]

In 2004, the SFPUC prepared a study to evaluate ecological risk from sediment quality around Yosemite Slough.[517] Sampling occurred between 1998 and 2001, and 32 samples were collected in the slough. Samples were taken up to a depth of four feet below ground surface (bgs). Chemical analyses included heavy metals, PCBs, PAHs, and chlorinated pesticides. Sample data were compared to data from six reference sites in the Bay, as well as Effects Range-Medians (ERMs).[518]

Mercury and nickel in surface samples exceeded SFPUC reference site concentrations and ERMs; however, even the SFPUC reference sites exceeded the nickel ERM.[519] Most other heavy metal concentrations were elevated compared to reference site concentrations, but did not exceed ERMs. Subsurface metals concentrations generally decreased with depth, and generally concentrations below two feet were consistent with SFPUC reference site surface sediment concentrations.

No surface sediment samples collected from Yosemite Slough exceeded the PAH ERM, and only one subsurface sample exceeded the PAH ERM. Most surface samples for PCBs exceeded the ERM, and all samples were at least an order of magnitude higher than the mean SFPUC reference site concentration. For subsurface samples, generally the highest concentrations were in the surface to one-foot deep (one foot bgs) core samples, and PCB ERMs were exceeded in almost all cases.

Many chlorinated pesticides were not detected above the analytical practical quantification limit.[520] Total chlordane, DDT, and dieldrin were detected most frequently in samples. All concentrations were elevated compared to the SFPUC reference site mean concentrations, and most mean concentrations exceeded ERMs.[521] Therefore, these data indicate that sediments in Yosemite Slough have been adversely impacted by historic land uses, and sediment quality (for mercury and organic chemicals) could impair the beneficial uses of the Bay.

---

[515] According to SFEI, toxic hot spots can be defined as: "Locations in enclosed bays, estuaries, or the ocean where pollutants have accumulated in the water or sediment to levels which (1) may pose a hazard to aquatic life, wildlife, fisheries, or human health, (2) may impact beneficial uses, or (3) exceed State Water Resources Control Board or Regional Water Quality Control Board-adopted water quality or sediment quality objectives." [520] The lowest level of certainty that can be reliably achieved within specified limits of precision and accuracy during routine laboratory operating conditions.

[521] San Francisco Public Utilities Commission (SFPUC), Draft Final Sediment Investigation at Yosemite Creek, October 1998-May 2000, July, 2004.

As noted in Section III.K, a shoreline investigation of sediment contamination was conducted for the 440 acres of underwater land surrounding all portions of the HPS Phase II site to the north, east, south, and southwest. This investigation evaluated whether contamination in Parcels E and E-2 had the potential to migrate (or had migrated) to sediments in the adjacent offshore area or to affect benthic invertebrates, birds, and mammals in the shoreline area. Copper, mercury, and PCBs were identified as the primary risk drivers. These chemicals exceeded concentrations considered safe for benthic invertebrates directly exposed to sediment. PCBs also were shown to cause potential risk to humans if they were to consume shellfish collected at HPS Phase II. However, results of statistical comparisons of fish tissue data at HPS Phase II indicated the potential PCBs risk at HPS Phase II was similar to regional levels.[522] The report concluded that no unacceptable ecological risk was indicated by sediments in India Basin or the wetlands east of the Slough.

Groundwater Quality

Portions of the Islais Valley, Visitacion Valley, and South San Francisco groundwater basins underlie the Project site. Existing designated beneficial uses are industrial service and process supplies.[523] Potential beneficial uses of these groundwater basins include municipal and domestic supplies (drinking water) and agricultural supplies; however, the underlying groundwater is not suitable as a drinking water supply.[524]

Principal contaminants in groundwater come from both nonpoint and point sources and include nitrates, pesticides, and industrial chemicals such as solvents.[525] Most groundwater contamination is local in scale.[526] The majority of groundwater pollutants from nonpoint sources[527] are salts and nitrates, which adversely affect approximately 10 to 15 percent of California's water wells, followed by pesticides and industrial contaminants.[528] Pathogens can also migrate to groundwater and contaminate groundwater resources.[529] These contaminants, often associated with septic systems and animal wastes, are transported by water percolating from the soil to the water table, where they enter the groundwater.[530]

---

[522] Health concerns associated with fish consumption in San Francisco Bay is a regional issue. Concentrations of six chemicals or groups—including mercury, PCBs, dioxins, dieldrin, DDT, and chlordane in fish collected throughout the San Francisco Bay—are elevated enough to pose a potential risk to recreational anglers and have resulted in health advisory warnings.
Barajas and Associates, *Final Feasibility Study Report for Parcel F Hunters Point Shipyard,* April 30. 2008; Jonas and Associates, *Final Second Five-Year Review of Remedial Actions Hunters Point Shipyard*, November 11, 2008. [529] Ibid.
[530] Ibid.

The degree of groundwater pollution from point and nonpoint sources depends on a number of factors:[531]

- **Point Sources (PSs)**—The number and intensity of point sources discharge directly to groundwater or to land surfaces.
- **Nonpoint sources (NPSs)**—The number and intensity or strength of NPS pollution activities within the source area of a well or a spring. A large number of low-grade NPS pollution sources may have a cumulative effect similar to that of a few more-intense NPS pollution sources.
- **Percolation rate**—The rate of percolation from the land surface to groundwater. A significant amount of chemicals or pathogens may reach groundwater when the water percolation rate is high.
- **Natural attenuation**—The ability of the soil or aquifer to retain or degrade the chemical before it reaches a well, spring, stream, or lake. The more a chemical is degraded or retained in the subsurface, the less likely it will be to reach a nearby well or stream. This is also a function of the pollutant; certain pollutants are more likely to be retained or degraded compared to others that are readily transported to or within groundwater.

Groundwater beneath the Project site flows from the west towards the Lower Bay.[532] As it passes beneath the Project site, it may become contaminated with bacteria and nutrients from leaky sewers, septic tanks, lawn fertilizers, pet waste, and other sources.[533] Historic land uses within the Project site may have resulted in the contamination of soil or groundwater with hazardous materials, as noted in Section III.K. Finally, groundwater near the shoreline may also mix with saltwater that ebbs and flows into coastal waters with the pull of the tides.[534] Local anomalies in groundwater elevation can also be caused by the interaction of subsurface utilities (sanitary sewer, storm sewer, and water supply lines) with the regional groundwater regime.[535] Storm/sanitary sewer lines and backfill in the utility trenches can serve as preferential pathways for groundwater flow and can either discharge or receive water.[536] Local anomalies in groundwater elevation have also been caused by groundwater injection/extraction activities associated with treatability studies.[537,538]

[536] Ibid.
[537] Ibid.
[538] Treatability studies are pilot-scale type tests conducted at hazardous wastes sites to determine if a treatment technology will work for that site's particular set of environmental conditions. Such studies have been conducted at HPS Phase II to address the sources of contamination described in Section K, Hazards and Hazardous Materials.

DWR has limited information on the water quality of the groundwater basins underlying the Project site, but indicates that elevated nitrate concentrations are the most common water quality problem with wells in the San Francisco Peninsula. High chloride concentrations were also observed in some wells.[539]

Within the boundaries of the Project site, there are numerous locations where the underlying groundwater has been affected by releases of various inorganic and organic constituents associated with current and previous land uses, as noted in Section III.K. Figure III.M-6 (Existing Groundwater Contamination) depicts the locations of groundwater contamination at the Project site as well as inferred depth to groundwater. Groundwater remediation within these areas is at various stages of completion.

Only low levels of a few organic compounds have been detected in groundwater beneath Candlestick Point. However, the portions of Candlestick Point bayward of the high tide elevation are covered with fill material that may contain hydrocarbons, heavy metals, oil and grease, and semi-volatile organic compounds (SVOCs).

The primary contaminants found in groundwater associated with HPS Phase II include volatile organic compounds (VOCs), SVOCs, total petroleum hydrocarbons (TPH), polychlorinated biphenyls (PCBs), pesticides, cyanide, metals, and radionuclides.[540] VOCs and certain metals have exceeded water quality criteria in groundwater at HPS Phase II. The landfill on HPS Phase II also contains radium dials that could contribute to groundwater contamination.[541] Potential threats may also be presented by off-gas from VOCs, particularly vinyl chloride, present in hot spots in soil and groundwater. [542] The Navy's Radiological Defense Laboratory program operated at HPS Phase II from the 1940s to 1969, and various radionuclides, primarily radium 226 and cesium 137, have also been found in the groundwater.[543]

Refer to Section III.K for further discussion of groundwater quality conditions related to hazardous materials contamination and remediation activities.

III.M.3 Regulatory Framework

Federal

Clean Water Act

The *Clean Water Act of 1977* (CWA) (33 US Code [USC] Section 1251 et seq.), which amended the federal *Water Pollution Control Act of 1972*, established the basic structure for regulating discharges of pollutants into waters of the United States (not including groundwater) and waters of the State of California. Waters of the United States (defined in 40 CFR 230.3(s)) include water bodies that are used in interstate or foreign

EXISTING GROUNDWATER CONTAMINATION

commerce, waters which are subject to the ebb and flow of the tide, interstate waters, tributaries of such waters, and wetlands adjacent to such waters. Waters of the State are defined by the SWRCB as any surface water or groundwater, including saline waters, within the boundaries of the State. Examples include, but are not limited to, rivers, streams, lakes, bays, marshes, mudflats, unvegetated seasonally ponded areas, drainage swales, sloughs, wet meadows, natural ponds, vernal pools, diked baylands, seasonal wetlands, and riparian woodlands. Impacts to waters of the United States and impacts to waters of the State can differ because of the differing laws and regulations that address these impacts. As interpreted by the regional USEPA and SWRCB, CWA permits and other regulatory mechanisms may refer to only one of the two categories. For example, CWA Section 401 Water Quality Certifications apply to waters of the State, while NPDES permits apply to waters of the United States.

The CWA delegates authority to the USEPA to implement pollution control programs. Under the CWA, it is unlawful for any person to discharge any pollutant from a point source into navigable waters, unless a NPDES permit is obtained. In addition, the CWA requires each state to adopt water quality standards for receiving water bodies and to have those standards approved by the USEPA. Water quality standards consist of designated beneficial uses for a particular receiving water body (e.g. wildlife habitat, agricultural supply, fishing etc.), along with water quality objectives necessary to support those uses.

CWA Section 303 Water Quality Standards

Section 303(c)(2)(b) of the CWA requires states to adopt water quality standards for all surface waters of the United States based on the water body's designated beneficial use. Where multiple uses exist, water quality standards must protect the most sensitive use. Water quality standards are typically numeric, although narrative criteria based upon biomonitoring methods may be employed where numerical standards cannot be established or where they are needed to supplement numerical standards. Water quality standards applicable to the Project are listed in the San Francisco Bay Basin Water Quality Control Plan Basin (Basin Plan) and are described in the Impacts discussion below.

CWA Section 303 Impaired Water Bodies and Total Maximum Daily Loads

Under CWA Section 303(d) of the CWA, the SWRCB is required to develop a list of impaired water bodies that do not meet water quality standards (promulgated under the National Toxics Rule or California Toxics Rule) after the minimum technology-based effluent limitations and water quality-based effluent limitations have been implemented for non-stormwater runoff permitted point sources. Lists are to be priority ranked for development of a total maximum daily load (TMDL). A TMDL is a calculation of the total maximum daily load (or "amount") of a pollutant that a water body can receive on a daily basis and still safely meet water quality standards. The SWRCB, Regional Water Quality Control Boards (RWQCB) and USEPA are responsible for establishing TMDL waste load allocations and incorporating approved TMDLs into water quality control plans, NPDES permits, and WDRs in accordance with a specified schedule for completion.

A mercury TMDL for San Francisco Bay has been completed, and on February 12, 2008, the USEPA approved a Basin Plan amendment incorporating the mercury TMDL into the Basin Plan.[544] A PCB TMDL

[544] San Francisco Bay Regional Water Quality Control Board (Water Board), website: http://www.swrcb.ca.gov/sanfranciscobay/water_issues/programs/TMDLs/sfbaymercurytmdl.shtml, accessed November 20, 2008.

has also been developed for San Francisco Bay and the SFRWQCB adopted a Basin Plan amendment on February 13, 2008, which is still pending final approval from the SWRCB and USEPA. A selenium TMDL is being developed for the North Bay (from the Sacramento-San Joaquin Delta to the central Bay), which is not in the vicinity of the Project site.

The mercury and PCB TMDLs include numeric targets for concentrations in suspended sediment and/or fish tissue. The TMDLs also include waste load allocations[545] for urban stormwater runoff and municipal and industrial wastewater discharges, with allocations apportioned for individual municipal separate storm sewer systems (MS4s)[546] and wastewater treatment plants including those in San Francisco. For stormwater, load reductions would be required to meet the TMDL waste load allocations within the 20 years required by the TMDLs. Load reduction efforts for TMDLs are implemented through municipal NPDES stormwater permits and individual NPDES permits (e.g., NPDES permit for water treatment plant discharges and others).

CWA Section 401 Water Quality Certification

Section 401 of the CWA specifies that states must certify that any activity subject to a permit issued by a federal agency, such as the USACE, meets all state water quality standards. In California, the SWRCB and the nine RWQCBs are responsible for taking certification actions for activities subject to any permit issued by the Corps pursuant to Section 404 (or for any other Corps' permit, such as permits issued pursuant to Section 10 of the *Rivers and Harbors Act of 1899*). Such certification actions, also known as 401 certification or water quality certification, include issuing a 401 certification that the activity subject to the federal permit complies with state water quality standards, issuing a 401 certification with conditions, denying 401 certification, or denying 401 certification without prejudice, should procedural matters preclude taking timely action on a 401 certification application. If 401 certification is denied, the permit pertaining to the proposed federal action is denied as well.

In practice, most RWQCBs rely on applications for Section 401 certification to evaluate whether WDRs would also need to also be issued for a project. The RWQCB must review final CEQA documentation prior to taking an action on an application for water quality certification and/or WDRs.

CWA Section 402 Stormwater NPDES Permits

Section 402(p) of the CWA regulates point source discharges of pollutants under the NPDES program. This section of the CWA was amended in 1987 to require the USEPA to establish regulations for permitting of municipal and industrial stormwater discharges (including discharges from active construction sites) under the NPDES permit program. The USEPA published final regulations for industrial and municipal stormwater discharges on November 16, 1990. The NPDES program requires all industrial facilities and municipalities of a certain size that discharge pollutants into waters of the United States to obtain a permit. Stormwater discharges into the San Francisco Bay region are commonly controlled through general and individual

[545] The maximum load of pollutants each discharger of waste is allowed to release into a particular waterway. Discharge limits are usually required for each specific water quality criterion.
[546] A Municipal Separate Storm Sewer System (MS4) is a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, man-made channels, or storm drains): (i) designed or used for collecting or conveying storm water; (ii) which is not a combined sewer; and (iii) which is not part of a Publicly Owned Treatment Works. The term MS4 also refers to the jurisdiction that operates such a system.

NPDES permits, which are adopted by the SWRCB (general permits) or SFRWQCB (individual permits), and are administered by the SFRWQCB. Water quality criteria in NPDES permits for discharges to receiving waters are based on criteria specified in the National Toxics Rule, the California Toxics Rule, and Basin Plans (discussed below). The USEPA requires NPDES permits to be revised to incorporate waste load allocations for TMDLs when the TMDLs are approved by USEPA (40 CFR 122).

CWA Section 402 Combined Sewer Overflow Control Policy

Combined sewer facilities are subject to Section 402(q) of the CWA, which codified the Combined Sewer Overflow Control Policy. Wet weather flows are governed by compliance with the nine minimum controls and long-term control plan requirements contained in the CSO Control Policy (59FR 18688-18698) and further described in Combined Sewer Overflows, Guidance for Nine Minimum Controls, USEPA 832-B-95-003 (May 1995). Communities with combined sewer systems are also expected to develop long-term CSO control plans that will ultimately provide for full compliance with the CWA, including attainment of water quality standards. The SFPUC implemented a Long-Term Control Plan (per the conditions of its NPDES Wastewater Discharge Permit) during the mid-1990s. The general goals for combined sewer systems under the CSO Control Policy are to provide storage capacity for wet weather flows, to maximize flow to treatment facilities, and to minimize CSO discharges. The requirements of the CSO Policy are implemented through the City's NPDES permits issued by the SFRWQCB.

CWA Section 404 Discharge of Fill or Dredge Materials

Section 404 of the CWA regulates temporary and permanent fill and disturbance of wetlands and waters of the United States. The discharge (temporary or permanent) of dredged or fill material into waters of the United States, including wetlands, typically requires authorization from USACE pursuant to Section 404 of the CWA through either a Nationwide (general categories of discharges with minimal effects) or Individual Permit. USACE-regulated activities under Section 404 involve the discharge of dredged or fill material, including, but not limited to, grading, placing riprap for erosion control, pouring concrete, laying sod, and stockpiling excavated material, into waters of the United States. Activities that generally do not involve a regulated discharge (if performed specifically in a manner to avoid discharges) include driving pilings, some drainage channel maintenance activities, constructing temporary mining and farm/forest roads, and excavating without stockpiling. The USEPA and the USACE have issued Section 404(b)(1) Guidelines (40 CFR 230) that regulate dredge and fill activities, including the water quality aspects of such activities. Subpart C Sections 230.20 through 230.25 contain water quality regulations applicable to dredge and fill activities. Among other topics, these guidelines address discharges that alter substrate elevation or contours, suspended particulates, water clarity, nutrients and chemical content, current patterns and water circulation, water fluctuations (including those that alter erosion or sediment rates), and salinity gradients.

River and Harbors Act Section 10

The *Rivers and Harbors Acts of 1890* (superseded) and *1899* (33 USC 401, et seq.) are the legislative origin of the USACE regulatory program. Various sections establish permit requirements to prevent unauthorized obstruction or alteration of any navigable water of the United States. Regulations implementing Section 10 of the *Rivers and Harbors Act* are coordinated with CWA Section 404 regulations. Section 10 (33 USC 403) covers construction, excavation, or deposition of materials in, over, or under such waters, or any work which would affect the course, location, condition, or capacity of those waters. Activities requiring Section 10

permits include structures (e.g., piers, wharfs, breakwaters, bulkheads, jetties, weirs, transmission lines) and work such as dredging or disposal of dredged material, or excavation, filling, or other modifications to the navigable waters of the United States. Bridge construction does not require a Section 10 permit, but does, however, require authorization for discharges of fill or dredge material under CWA Section 404.[547]

Executive Order 11988-Floodplain Management

Executive Order 11988 requires federal agencies to recognize the values of floodplains and to consider the public benefits of restoring and preserving floodplains. Under this order, the USACE has the responsibility for reviewing flood protection projects that may affect navigable waters. The USACE is required to take action and provide leadership to avoid development in the base floodplain; reduce the risk and hazard associated with floods; minimize the impact of floods on human health, welfare, and safety; and restore and preserve the beneficial and natural values of the base floodplain.

National Flood Insurance Act and Flood Disaster Protection Act

The *National Flood Insurance Act of 1968* and the *Flood Disaster Protection Act of 1973* were enacted to reduce the need for flood protection structures and to limit disaster relief costs by restricting development in floodplains. FEMA was created in 1979. One of its duties is to administer the NFIP and to develop standards for fluvial and coastal floodplain delineation. The NFIP is a federal program enabling property owners in participating communities to purchase insurance as protection against flood losses in exchange for state and community floodplain management regulations that reduce future flood damages.[548]

The preliminary FIRM for San Francisco identifies several areas along the San Francisco bayfront, including Bayview Hunters Point, HPS Phase II, and Candlestick Point as coastal flood hazard zones, including a Zone A designation (in areas subject to inundation by tidal surge) and a Zone V designation (high coastal flooding zones subject to wave hazards) (SFHAs). Refer to Figure III.M-4. The City Administrator has submitted comments on the preliminary FIRM to FEMA, which questions the inclusion of portions of the Project site in a Zone V SFHA. The City Administrator has suggested it may seek a variance from FEMA if a final FIRM retains the SFHAs identified on the preliminary FIRMs. If the Project site is deemed to be within an area defined as a SFHA on a final FIRM, published prior to development of the Project, the Project would be subject to applicable floodplain development requirements.

State

Responsibility for the protection of water quality in California resides with the State Water Resources Control Board (SWRCB) and nine Regional Water Quality Control Boards (RWQCBs). The SWRCB establishes statewide policies and regulations for the implementation of water quality control programs mandated by federal and state water quality statutes and regulations. The RWQCBs develop and implement Water Quality Control Plans (Basin Plans) that consider regional beneficial uses, water quality characteristics, and water quality problems. The San Francisco Bay Region Regional Water Quality Control

[547] California Natural Resources Agency, website: http://ceres.ca.gov/wetlands/permitting/RHA_summary.html, accessed July 16, 2009.
[548] Federal Emergency Management Agency, National Flood Insurance Program, Available at: www.fema.gov/business/nfip/, Accessed: June 19, 2008.

Board (SFRWQCB) implements a number of federal and State laws, the most important of which are the *State Porter-Cologne Water Quality Control Act* and the federal CWA.

Porter-Cologne Water Quality Control Act

The *Porter-Cologne Water Quality Control Act* (PCWQCA) is the principal law governing water quality in California. Under the PCWQCA, the SWRCB and the nine RWQCBs were established as statewide and regional water quality planning agencies, respectively. The PCWQCA requires the development of statewide and regional Water Quality Control Plans (Basin Plans) to protect the quality of surface water and groundwater. The SWRCB and RWQCBs are required to designate beneficial uses of surface waters and groundwater, establish water quality objectives to protect beneficial uses, and develop implementation programs to meet the water quality objectives. The SWRCB and RWQCBs have permitting and enforcement authority to prevent and control waste discharges that could affect waters of the state through the issuance of NPDES permits and WDRs. The Project site is located in the San Francisco Bay Basin and subject to regulatory requirements of the SFRWQCB.

State Implementation Plan for Toxics Standards for Surface Waters

In March 2000, the SWRCB adopted the State Implementation Plan (SIP) in Resolution No. 2000-015. The SIP establishes (1) implementation provisions for priority pollutant criteria promulgated by the USEPA through the National Toxics Rule (40 CFR 131.36) (promulgated on December 22, 1992 and amended on May 4, 1995) and through the California Toxics Rule (40 CFR 131.38) (promulgated on May 18, 2000 and amended on February 13, 2001), and for priority pollutant objectives established by RWQCBs in their Water Quality Control Plans; (2) monitoring requirements for 2,3,7,8-TCDD equivalents (dioxin); and (3) chronic toxicity control provisions. In addition, this policy includes special provisions for certain types of discharges and factors that could affect the application of other provisions in this policy. A list of priority pollutants and associated criteria can be found in the CFR, Section 40, Part 131 (Water Quality Standards: Establishment of Numeric Criteria for Priority Toxic Pollutants for the state of California, May 18, 2000).

California Toxics Rule (CTR)

In cases where the Basin Plan does not contain a standard for a particular pollutant, other criteria are used to establish a standard. These may be applied from SWRCB documents (e.g., the Inland Surface Waters Plan and the Pollutant Policy Document) or from water quality criteria developed under Section 304(a) of the CWA (e.g., California Toxics Rule). Numeric criteria are required by the CWA for many priority toxic pollutants. However, in 1994, a state court overturned the state's water quality control plans containing water quality criteria for priority toxic pollutants. To address the issue of toxic pollutants, on May 18, 2000, the USEPA promulgated the California Toxics Rule based on the Administrator's determination that numeric criteria are necessary in the State of California to protect human health and the environment. These federal criteria are numeric water quality criteria for priority toxic pollutants and other provisions for water quality standards legally applicable in the state of California for inland surface waters, enclosed bays, and estuaries for all purposes and programs under the CWA.

Waste Discharge Requirements (WDRs) Program

Under the PCWQCA, the RWQCBs regulate the "discharge of waste" to "waters of the State". All parties proposing to discharge waste that could affect waters of the state must file a report of waste discharge (ROWD) with the appropriate RWQCB. The RWQCB then responds to the ROWD by issuing WDRs in a public hearing, or by waiving WDRs (with or without conditions) for the proposed discharge.

Both of the terms "discharge of waste" and "waters of the State" are broadly defined in the PCWQCA, such that discharges of waste include fill, any material resulting from human activity, or any other discharge that may directly or indirectly impact waters of the State. While all waters of the United States that are within the borders of California are also waters of the State, the converse is not true; waters of the United States are a subset of waters of the State.

While Section 404 permits and 401 certifications are required when the an activity results in fill or discharge directly below the ordinary high water line of waters of the United States, any activity that results or may result in a discharge that directly or indirectly impacts waters of the state or the beneficial uses of those waters are subject to WDRs. In practice, most RWQCB rely on applications for 401 certification to determine whether WDRs also need be issued for a proposed project. The SFRWQCB has produced a combined 401 certification/waiver of WDRs application form to ensure that applicants do not need to file both a ROWD and an application for 401 certification. WDRs for discharges directly to surface waters are also NPDES permits.

Anti-Degradation Policy

A key policy of California's water quality program is the State's Antidegradation Policy. This policy, formally known as the Statement of Policy with Respect to Maintaining High Quality Waters in California (SWRCB Resolution No. 68-16), restricts degradation of surface and ground waters. In particular, this policy protects water bodies where existing quality is higher than necessary for the protection of beneficial uses. Under the Antidegradation Policy, any actions that can adversely affect water quality in all surface and ground waters must (1) be consistent with maximum benefit to the people of the state; (2) not unreasonably affect present and anticipated beneficial use of the water; and (3) not result in water quality less than that prescribed in water quality plans and policies, (i.e., will not result in exceedances of water quality objectives).[549]

Construction General Permit

Pursuant to the CWA Section 402, discharges from construction projects are prohibited unless such practices comply with an NPDES permit. The SWRCB adopted a statewide *NPDES General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities* (Construction General Permit) (Order No. 2009-0009-DWQ, NPDES No. CAS000002) on September 2, 2009 to meet CWA requirements and the water quality goals of the PCWQCA. Every construction project that disturbs one or more acres of land surface (or that is part of a common plan of development or sale that disturbs more than one acre of land) requires coverage under the Construction General Permit. To obtain coverage under

[549] SWRCB, 1968, Statement of Policy with Respect to Maintaining High Quality of Waters in California. Resolution No. 68-16.

the Construction General Permit, the landowner or other applicable entity must file Permit Registration Documents (PRDs) prior to the commencement of construction activity, which include a Notice of Intent (NOI), Storm Water Pollution Prevention Plan (SWPPP), and other documents required by the Construction General Permit. Every regulated construction project is required to seek coverage under the new Construction General Permit by July 1, 2010. Because the Project would disturb more than one acre, construction of the Project would be subject to the Construction General Permit requirements.

Construction activities subject to the Construction General Permit include clearing, grading, and disturbances to the ground, such as stockpiling or excavation, that result in soil disturbances of at least one acre of total land area. The SWPPP that must be prepared by every individual construction project under the Construction General Permit has two major objectives: (1) to help identify the sources of sediment and other pollutants that affect the quality of stormwater discharges; and (2) to describe and ensure the implementation of BMPs to reduce or eliminate sediment and other pollutants in stormwater, as well as non-stormwater discharges. BMPs must be implemented to meet the performance standard of Best Available Technology/Best Conventional Technology (BAT/BCT).[550]

The Construction General Permit requires specific minimum BMPs, depending upon the project sediment risk (Risk Level 1 through 3). Sediment risk is determined based on the sensitivity of the receiving water to sediment and the potential for site erosion and sediment transport. For moderate sediment risk projects (Risk Level 2), Numeric Action Levels (NALs) for turbidity and pH are imposed, and for high sediment risk projects (Risk Level 3), Numeric Effluent Limitations (NELs) for turbidity and pH are imposed. Post-construction stormwater performance standards are also included for sites not covered by a municipal stormwater permit. The Construction General Permit requires effluent and receiving water (only for some Risk Level 3 sites) monitoring to demonstrate compliance with permit requirements, and corrective action must be taken if these limits are exceeded. The results of monitoring and corrective actions must be reported annually to the SWRCB. This permit also specifies minimum qualifications for SWPPP developers and construction site inspectors.

Industrial General Permit

Pursuant to the CWA Section 402(p), the SWRCB has issued a statewide *NPDES General Industrial Permit for Discharges of Storm Water Associated with Industrial Activities* (Industrial General Permit)(Order No. 97-03-DWQ, NPDES General Permit No. CAS000001). A wide range of industries is covered under the Industrial General Permit, as determined by the facility Standard Industrial Classification (SIC) code, a four-digit code that refers to the type of business conducted.

The Industrial General Permit requires control of pollutant discharges using BAT/BCT to meet water quality standards specified in the Basin Plan. The Industrial General Permit generally requires facility operators to (1) eliminate unauthorized non-stormwater discharges; (2) develop and implement a SWPPP; and (3) perform monitoring of stormwater discharges and authorized non-stormwater discharges.

[550] As defined by USEPA, Best Available Technology (BAT) is a technology-based standard established by the CWA as the most appropriate means available on a national basis for controlling the direct discharge of toxic and non-conventional pollutants to navigable waters. The BAT effluent limitations guidelines, in general, represent the best existing performance of treatment technologies that are economically achievable. Best Conventional Technology (BCT) is a technology-based standard that applies to treatment of conventional pollutants, such as total suspended solids.

In 2005, the SWRCB issued a Draft Final Industrial General Permit that revises the current permit from 1997. Significant changes include modifications to SWPPP requirements, the monitoring program, and group monitoring requirements. In addition, the Draft Final Permit includes parameter benchmarks[551] for certain indicator parameters based on USEPA's Multi-Sector Permit, as an additional method to evaluate the effectiveness of BMPs. Under the current 1997 permit, light industry was excluded from coverage if there was no exposure of industrial materials to stormwater. Under the Draft Final permit, such facilities would not be automatically excluded from coverage but would need to apply for a Conditional Exclusion. To obtain this exclusion, dischargers must submit a certification for a Conditional Exclusion to demonstrate that there would be no contact of pollutants with stormwater.

Industrial stormwater discharges from HPS Phase II are regulated under the Industrial General Permit. It is possible that future tenants within the Project site may include industrial facilities that would be covered under the Industrial General Permit. For example, a marina classified as SIC 4493 is required to obtain coverage under the Industrial General Permit if vehicle maintenance activities such as rehabilitation, mechanical repairs, painting, fueling, and lubrication or equipment cleaning operations are conducted.

Municipal Stormwater General Permit

The SWRCB regulates discharges from MS4s under a Phase I program for medium and large municipalities (serving 100,000 or more people) and under a Phase II program for small municipalities (serving 100,000 or less people), and governmental facilities such as military bases and public campuses. The relatively small portions of the City that drain to MS4 areas (approximately 10 percent of the City) are regulated under the statewide *Phase II NPDES General Permit for Storm Water Discharges from Small MS4s* (Municipal Stormwater General Permit)(Order No. 2003-0005-DWQ).

In accordance with the Municipal Stormwater General Permit, the City must develop, implement, and enforce a program to address stormwater runoff from new development and redevelopment projects that disturb greater than or equal to one acre, including projects less than one acre that are part of a larger common plan of development or sale, that discharge into the MS4 by ensuring that post-construction controls are in place that would prevent or minimize water quality impacts. The Municipal Stormwater General Permit requires covered municipalities to prepare a Stormwater Management Plan (SWMP) with the goal of reducing the discharge of pollutants to the maximum extent possible (MEP), as defined in and implemented by the General Permit. The MEP approach is an ever evolving, flexible, and advancing

[551] The Draft Final 2005 Industrial General Permit contains parameter benchmark concentrations for constituents commonly found in stormwater runoff from industrial facilities (indicator parameters), which are derived from USEPA's Multi-Sector General Permit; the Multi-Sector General Permit provides coverage for industrial facilities located in five states, in certain Native-American lands, as well as for various federal facilities, where USEPA is the NPDES permit authority. The benchmarks are not numeric effluent limits; however, the benchmarks represent pollutant concentrations above which are levels of concern. The benchmarks will be used in the Draft Final Permit to evaluate if the facility's Best Management Practices (BMPs) are effective in reducing concentrations of pollutants, but are not intended to be used to determine whether or not discharges are causing or contributing to a water quality impairment. The Draft Final Permit requires that if runoff concentrations are above one or more benchmarks, the discharger must revise its Storm Water Pollution Prevention Plan (SWPPP) to include more effective BMPs, and collect samples from the next two consecutive qualifying storms. Industrial facilities regulated under the Industrial General Permit are currently not subject to the parameter benchmarks; however the benchmarks will take effect when the Draft Final Permit is adopted.

concept, which considers technical and economic feasibility. Consequently, the definition of MEP evolves with an increased knowledge about controlling urban runoff.

In accordance with the Municipal Stormwater General Permit, the SWMP must describe Minimum Control measures—BMPs, measurable goals, and timetables for implementation—in the following six program areas: (1) Public Education; (2) Public Participation; (3) Illicit Discharge Detection and Elimination; (4) Construction Site Storm Water Runoff Control; (5) Post Construction Stormwater Management; and (6) Pollution Prevention/Good Housekeeping for Municipal Operations.

The SFPUC has prepared a SWMP that establishes a framework for achieving the MEP standard for the discharge of pollutants from MS4s within their jurisdiction in accordance with the Phase II stormwater regulations. Additionally, the City has developed Draft San Francisco Stormwater Design Guidelines in compliance with the Municipal NPDES Permit requirements that are expected to be approved and adopted by December 2009.

In the operational phase of the Project, stormwater discharging to areas served by the combined sewer system would be regulated under the Wastewater Discharge NPDES Permit, described further below. However, at build out, the Project site would be served by a separate storm sewer system and subject to the requirements of the Municipal Stormwater General Permit and associated SWMP and San Francisco Stormwater Guidelines, described further below.

Recycled Water General Permit for Landscape Irrigation

In July 2009, the SWRCB released General Waste Discharge Requirements for Landscaping Irrigation Uses of Municipal Recycled Water (Recycled Water General Permit), allowing municipal entities to distribute disinfected tertiary-treated recycled water to select customers for landscape irrigation (Order No. 2009-0006-DWQ). The Recycled Water General Permit is intended to further the state's Recycled Water Policy (*California Code of Regulations* [CCR] Title 22) and *California Water Code* Section 13552.5, both of which encourage recycled water for non-potable uses.

Under the Recycled Water General Permit, "recycled water" is limited to recycled water produced by a public entity at a municipal wastewater treatment plant. The Recycled Water General Permit does not apply to water produced from the treatment of other non-municipal wastewaters (e.g., oil field production, food processing, stormwater, etc.) and other types of treatment facilities (e.g., industrial wastewater treatment plants). To obtain coverage under the Recycled Water General Permit, the producer/distributor of recycled water must submit a Notice of Intent (NOI) and Operations and Maintenance Plan to the SWRCB. The Operations and Maintenance Plan must contain a detailed operations plan for use areas, including procedures for implementation of regulations regarding recycled water use and maintenance of equipment and emergency backup systems to maintain compliance with the conditions of the Recycled Water General Permit. In addition, it must have an irrigation management plan specifying measures to ensure that recycled water is applied efficiently, at an agronomic rate, and using practices necessary to minimize application of salinity constituents to use areas. Characteristics of the soil, the recycled water, plant species being irrigated, climatic conditions, and other relevant conditions must be considered in this plan.

The Recycled Water General Permit notes that the use of recycled water may not be appropriate for all scenarios because of unique site-specific characteristics and conditions. In addition, because there are

certain public health concerns associated with recycled water, the Recycled Water General Permit includes exposure control measures, including minimum setback distances, signage, method of application, and use restrictions and only allows use of water treated to CCR Title 22 tertiary treatment requirements. Other potential public health issues, such as cross-contamination of recycled water and potable water sources, control of recycled water salinity, and chlorination are regulated under the Recycled Water Policy and the *Water Code*. If the Project would use recycled water, landscape irrigation with recycled water would require coverage under this Recycled Water General Permit or an individual permit.

SWRCB Low Impact Development Policy

On January 20, 2005, the SWRCB adopted the Low Impact Development (LID) Policy which, at its core, promotes the idea of "sustainability" as a key parameter to be prioritized during the design and planning process for future development. The SWRCB has directed its staff to consider sustainability in all future policies, guidelines, and regulatory actions.

The sustainability practice promotes LID to benefit water supply and contribute to water quality protection. LID has been a proven approach in other parts of the country and is seen in California as an alternative to conventional stormwater management. The RWQCBs are advancing LID in California in various ways, including provisions for LID requirements in renewed Phase I municipal stormwater NPDES permits.

San Francisco Bay Basin Plan

As a function of the PCWQCA, the Basin Plan[552] identifies the beneficial uses, water quality objectives, and actions necessary to control non-point and point sources of pollution to receiving waters in the San Francisco Bay region. Existing and potential beneficial uses for the Lower Bay, as identified in the Basin Plan, are industrial service supply; ocean, commercial and sport fishing; shellfish harvesting; estuarine habitat; fish migration; preservation of rare and endangered species; fish spawning; wildlife habitat; water contact recreation; non-contact water recreation; and navigation. Existing and potential beneficial uses of the Islais Valley, South San Francisco, and Visitacion Valley groundwater basins are municipal and domestic water supply (potential), industrial process water supply (existing), industrial service water supply (existing), and agricultural water supply (potential).

Basin Plan narrative and numeric water quality objectives are used to define appropriate levels of environmental quality and to control activities that could adversely affect individual aquatic systems and the Bay Basin in general. The narrative water quality objectives describe pollution conditions to be avoided but no numeric limit is imposed. The numeric water quality objectives describe the maximum concentrations of a given pollutant that can remain in a body of water without adversely affecting the aquatic system. Beneficial uses, together with applicable water quality objectives, comprise the relevant water quality standards.

[552] California Regional Water Quality Control Board San Francisco Bay Region (SFRWQCB), *2007,* op. cit.

Water Quality Control Plan for Enclosed Bays and Estuaries

The SWRCB adopted Part 1 of the Water Quality Control Plan for Enclosed Bays and Estuaries in August, 2009 to comply with the requirements of *California Water Code* Section 13393 to adopt State sediment quality objectives (SQOs). Part 1 integrates chemical and biological measures to accomplish two narrative SQOs: (1) to protect human health, and (2) to ensure that pollutants in sediments are present in quantities that, alone or in combination, are not toxic to benthic[553] communities in enclosed bays and estuaries of California.[554] Part 1 is not intended to address low dissolved oxygen, pathogens, or nutrients, including ammonia.

The narrative SOQs are to be implemented through a multiple lines of evidence (MLOE) approach. The MLOE approach includes periodic assessment of three indicators ("lines of evidence"): sediment toxicity, benthic community condition, and sediment chemistry. Part 1 specifies testing and assessment procedures for these indicators as well as guidelines for interpretation. With respect to dredging, Part 1 states that the RWQCB "shall not approve a dredging project that involves the dredging of sediment that exceeds the objectives in Part 1." Moreover, the SWRCB must apply SQOs as receiving water limits if discharge of a toxic pollutant to bay or estuarine waters has the reasonable potential to cause or contribute to an exceedance of the SQOs. Exceedance of the SQO could constitute violation of an NPDES permit, such as a municipal stormwater permit.

Cleanup of contaminated sediment is subject to Resolution No. 92-49 (Policies and Procedures for Investigation and Cleanup and Abatement of Discharges under *Water Code* Section 13304). Part 1 also allows the RWQCB to develop site-specific sediment management guidelines where appropriate, for example, where toxic stressors have been identified and controllable sources of these stressors exist or remedial goals are desired.

Wastewater Discharge Permit (Combined Sewer System)

Discharges from the SWPCP, NPWWF, and BWWF are regulated under the NPDES permit[555] set forth in Order No. R2-2008-0007 and NPDES No. CA0037664. This NPDES permit does not apply to all wastewater collection systems and CSOs within the City and County of San Francisco, but is specific to the facilities referenced in this NPDES permit. Because the Project would discharge to these permitted facilities, the Wastewater Discharge Permit is an applicable WDR for evaluation of potential Project impacts.

This NPDES permit includes technology-based effluent limits for dry and wet weather discharges, water quality-based effluent limits for dry weather discharges from the SWPCP, receiving water limitations based on water quality objectives in the Basin Plan, and various additional provisions, such as monitoring and reporting program requirements. This NPDES permit also requires adherence to provisions consistent with the CSO Control Policy (refer to the above discussion under Federal CWA, Combined Sewer Overflow Control Policy), which include:

- Revision and update of a Combined Sewer System Operation and Maintenance Plan

[553] Living on or in bottom of the ocean, bays, and estuaries, or in the streambed.
[554] Enclosed bays include all bays where the narrowest distance between headlands or outermost harbor works is less than 75 percent of the greatest dimension of the enclosed portion of the bay. This definition includes San Francisco Bay.
[555] An NPDES Permit is also a waste discharge requirement (WDR).

- Implementation of the nine minimum technology-based controls
- Conduct proper operations and regular maintenance programs
- Maximize use of the collection system as inline storage capacity
- Review and modify the pretreatment program if practical and feasible
- Maximize the flow to the SWPCP and NPWWF during wet weather flow conditions
- Prohibit CSOs during dry weather
- Control solid and floatable materials by ensuring that overflows are baffled or volumes of floatables are reduced by other means, and removing materials captured in the storage/transport system prior to discharge to receiving waters
- Develop and implement a pollution prevention program focused on reducing the impact of CSOs on receiving waters
- Notify the public of overflows
- Monitor wet weather outfalls to effectively characterize overflow impacts and the efficacy of CSO controls

Long-Term Control Plan

The City has implemented the Long-Term Control Plan required by the CSO Policy by designing and constructing facilities to capture and treat 100 percent of the sewage and stormwater generated in combined sewer areas within the City. Provisions of the Long-Term Control Plan include:

Wet Weather Performance Criteria. The City designed its combined sewer system based on historical rainfall to achieve the long-term average goal of only one CSO event per year along the southeast sector of the City. This wet weather performance criteria is a long-term average and will not be used to determine compliance or non-compliance with the NPDES permit because rainfall patterns vary.[556]

Wet Weather Operation of Bayside Facilities. Specific activation and operation criteria for pump stations and facilities of the Bayside Facilities are required. Activation and operation of these facilities depends on rainfall, forecasts, and storage conditions in the North Drainage Basin and the Central Drainage Basin.

Post Rain Activities. Treatment at the SWPCP and NPWWF continues until North, Central and Southeast Drainage Basin storage/transports are substantially empty of stormwater flows.

The combined storm sewer treatment program, implemented by the City and the SFPUC in compliance with the CSO Control Policy and the NPDES permit, provides 100 percent capture and treatment of the combined sewer flows rather than the 85 percent minimum as required by the CSO Control Policy. San Francisco has no untreated overflow events because the combined flows receive the equivalent of primary treatment within the storage/transport boxes. Primary treatment of these overflows consists of removal of floatable materials and settleable solids. Portions of the Project site currently discharge both stormwater and wastewater to the combined storm sewer system.

[556] The SWRCB recognizes that some years are wetter than others and may contribute more flow than anticipated in the system design criteria.

Temporary Construction Dewatering Requirements for Separate Storm Sewer Areas

Generally speaking, for construction occurring in areas not served by a combined sewer system and depending on the nature and degree of residual groundwater contamination present when construction begins, temporary groundwater dewatering could be required and would be regulated under the Construction General Permit for minor amounts of dewatering of non-polluted groundwater; one of three NPDES general dewatering permits issued by the SFRWQCB, depending on the residual pollutants in a particular portion of a site; or an individual NPDES Permit/WDR if none of the General Permits are applicable. The three SFRWQCB dewatering general permits are as follows:

- Order No. R2-2004-0055 NPDES No. CAG912003, General Waste Discharge Requirements for: Discharge or Reuse of Extracted and Treated Groundwater Resulting from the Cleanup of Groundwater Polluted by Volatile Organic Compounds
- Order No. R2-2006-0075 NPDES No. CAG912002 General Waste Discharge Requirements for: Discharge or Reuse of Extracted and Treated Groundwater Resulting from the Cleanup of Groundwater Polluted by Fuel Leaks and Other Related Wastes at Service Stations and Similar Sites
- Order No. R2-2007-0033, NPDES No. CAG912004. General Waste Discharge Requirements for: Discharge or Reuse of Extracted Brackish Groundwater and Reverse Osmosis Concentrate Resulting from Treatment of Groundwater by Reverse Osmosis and Discharge and Reuse of Extracted and Treated Groundwater Resulting from Structural Dewatering.

The above general permits could also apply to the operational phase of a project if significant dewatering was required to the separate storm drain system within areas of contaminated groundwater or if long term dewatering were required (e.g., a below-grade parking lot installed below the local water table). If none of the dewatering general permits were applicable to a project or a specific temporary dewatering activity, an individual NPDES permit with WDRs could be required.[557]

Long-Term Management Strategy for the Placement of Dredged Material

In 1990 the USEPA, USACE, SWRCB, and BCDC joined with navigation interests, fishing groups, environmental organizations, and other interested parties to form the Long-Term Management Strategy (LTMS) program for dredged material from the San Francisco Bay Area. The LTMS provides the basis for uniform federal and state dredged material disposal policies and regulations. The California Coastal Conservancy, CDFG, and US Fish and Wildlife Service also participate in the LTMS as necessary to implement beneficial reuse options. The goals of the LTMS are to manage dredging and dredge material disposal in an economically and environmentally sound manner, maximize the beneficial use of dredged material, and develop a coordinated permit application review process for dredging and disposal projects. Specific guidance for conducting dredging and material disposal activities is summarized in the LTMS Management Plan.[558]

---

[557] Farhad Azimzadeh, San Francisco Bay Regional Water Quality Control Board, Enforcement, General Permits, Pretreatment Section, telephone communication with BASELINE Environmental Consulting, December 16, 2008.
[558] US Army Corps of Engineers, USEPA, BCDC, and Water Board, *Long-Term Management Strategy for the Placement of Dredged Material in the San Francisco Bay, Management Plan 2001.*

The Dredged Material Management Office (DMMO) was established as part of the LTMS to consolidate the processing of dredging permit applications by the staff of the LTMS agencies and the State Lands Commission. (The State Lands Commission holds title to all ungranted tide and submerged lands in California, including some tidelands and submerged lands in the Project site.) The DMMO provides a single application form that meets the requirements of its member agencies and unified processing of applications for dredging permits.

The process for obtaining approvals for dredging or dredge materials disposal has three phases: (1) suitability determination, (2) permit process, and (3) episode approval. The suitability determination process occurs at the DMMO level. The DMMO member agencies make a joint recommendation to the individual member agencies on whether the sediments to be dredged are appropriate, in terms of potential for environmental impacts, for the proposed disposal or reuse site. The recommendation is usually based on the results of sediment testing. The applicant must submit results from recent sediment testing or submit sufficient data to support a finding by the agencies that the sediments are suitable for the proposed disposal environment. The applicant should submit to the DMMO either a sediment Sampling and Analysis Plan and Quality Assurance Project Plan, or a written request (with supporting information) requesting an exclusion from testing requirements based on factors such as previous testing history and physical characteristics of the material proposed for dredging, if applicable. The applicant must submit the sampling results to the DMMO for review, and the DMMO would make a decision about where the materials can be disposed.

Section 404 of the CWA and BCDC's Bay Plan do not authorize aquatic disposal of dredged material unless an analysis of potential alternatives is first performed and the alternatives prove to be either environmentally unacceptable or infeasible. In order for projects proposing the discharge of dredged material to waters of the United States to be approved under Section 404 of the CWA, it must be shown that there is no practicable alternative to the proposed discharge that would have less impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences. Applicants for permits to dispose of dredge spoils must submit a written analysis of the alternatives to the DMMO. The DMMO has developed a list of questions to guide applicants in preparing the discussion.

Although the DMMO provides initial review of permit applications and suitability recommendations, applicants must eventually obtain separate approval from the appropriate DMMO member agencies (such as CWA Section 404 Permit from USACE, CWA Section 401 Water Quality Certification from the SFRWQCB, and approval by BCDC); each agency issues permit conditions and specific requirements about how the project is to be performed.

Some permits for maintenance dredging projects authorize multiple dredging and disposal episodes over a period of several years. Such permits require that permittees obtain formal approval, after a recommendation of suitability by the DMMO, for each dredging episode under the permit. Episode approvals, when required, are issued by the individual DMMO member agencies.

San Francisco Bay Conservation and Development Commission

The BCDC is a federally designated state coastal management agency for the San Francisco Bay. In accordance with the *McAteer-Petris Act of 1965*, the BCDC is responsible for maintaining and carrying out the policies of the San Francisco Bay Plan (Bay Plan). Bay shoreline construction projects, such as filling or dredging in the Bay, work adjacent to certain tributaries to the Bay, work adjacent to or within salt

ponds, and work adjacent to managed wetlands around the Bay, or grading within 100 feet of the Bay shoreline, require permit approval from the BCDC. The BCDC issues an Administrative Permit for minor repairs or improvements along the Bay shoreline and a Major Permit for more extensive projects.

The Bay Plan, adopted in 1969 and more recently amended in 2008, specifies goals, objectives and policies for existing and proposed waterfront land uses use and other BCDC jurisdictions. Part III of the Bay Plan contains findings and policies pertinent to the development of the Project.

The Project would involve the construction of a marina, a bridge across Yosemite Slough, and various shoreline improvements. Such activities would require a permit from BCDC.

Joint Aquatic Resources Permit Application

The Joint Aquatic Resources Permit Application (JARPA) process streamlines federal, state, and local environmental permitting processes for applicants proposing construction, fill placement, public access impingement, and other development activities that occur along the San Francisco Bay and the coastline, including projects near or in wetlands or creeks that flow to the Bay. Under the JARPA process, agencies that would regulate the Project such as the SWRCB, SFRWQCB, BCDC, and the California Department of Fish and Game (CDFG), receive the same permit application information, which may improve coordination between the agencies. Generally, the project must comply with CEQA requirements before various agencies issue permits under JARPA. Examples of certifications/permits that can be issued under JARPA include CWA Section 401 and Section 404 permits.

Local

City of San Francisco General Plan

Refer to Land Use and Plans of this EIR for a description of the General Plan. Objectives and policies relevant to water quality and hydrology are found in the Environmental Protection element and are listed below:

Objective 1	Achieve a proper balance among the conservation, utilization, and development of San Francisco's natural resources.	
	Policy 1.1	Conserve and protect the natural resources of San Francisco.
	Policy 1.2	Improve the quality of natural resources.
	Policy 1.4	Assure that all new development meets strict environmental quality standards and recognizes human needs.
Objective 2	Implement broad and effective management of natural resources.	
Objective 3	Maintain and improve the quality of the bay, ocean, and shoreline areas.	
	Policy 3.1	Cooperate with and otherwise support regulatory programs of existing regional, state, and Federal agencies dealing with the Bay, Ocean, and Shorelines.

Storm Water Management Plan

In January 2004, San Francisco completed a SWMP for those portions of the City discharging to MS4s, in compliance with the Municipal Stormwater General Permit.[559] The SWMP does not apply to those areas of the City where stormwater discharges into the combined sewer system, portions of Candlestick Point managed by the California Department of Parks and Recreation, or HPS Phase II, which is covered under the Industrial General Permit. Thus, at this time, only those portions of the Candlestick Point served by MS4s under the jurisdiction of the SFPUC would require compliance with the San Francisco SWMP. If development proceeded and separate storm sewer systems were installed, the Project site would become an MS4 area. Therefore, the entire Project site would require compliance with the San Francisco SWMP because the City must comply with the Municipal General Stormwater Permit conditions for MS4 areas. SWMP measures that could be applicable to the Project site would fall into five broad categories: (1) Public Education, (2) Public Participation, (3) Illicit Discharge Detection and Elimination, (4) Construction Site Storm Water Runoff Control, and (5) Post Construction Stormwater Management.

City of San Francisco Construction Site Water Pollution Prevention Program

The City of San Francisco Construction Site Water Pollution Prevention Program requires stormwater quality BMPs at all construction sites, regardless of the area of the site and whether the site drains to the combined or separate sewer system. Pollution prevention measures that must be implemented at all construction sites include:

- Develop SWPPP.
- Identify all storm drains and catch basins near the construction site and ensure all workers are aware of their locations to prevent pollutants from entering them.
- Protect all storm drain and catch basin inlets.
- Develop spill response and containment procedures.
- Inspect site regularly to ensure that BMPs are intact.
- Conduct daily site cleanings as needed.
- Educate employees and subcontractors about BMPs.
- Regularly maintain all BMPs at project site.

For sites that disturb one or more acres and drain to the separate sewer system, compliance with the Construction General Permit and preparation and implementation of a SWPPP that meets Construction General Permit conditions is required. For sites that discharge to the combined sewer system, a SWPPP that includes an Erosion and Sediment Control Plan and meets SFPUC requirements must be submitted.

San Francisco Green Building Ordinance

In 2008, the City adopted Chapter 13C (Green Building Requirements) into *San Francisco Building Code*. The purpose of the requirements is to promote the health, safety, and welfare of San Francisco residents, workers, and visitors by minimizing the use and waste of energy, water and other resources in the construction and operation of City's buildings and by providing a healthy indoor environment. The

[559] San Francisco Public Utilities Commission, *Storm Water Management Plan*, January 2004, available at: http://sfwater.org/mto_main.cfm/MC_ID/14/MSC_ID/361/MTO_ID/542 Accessed July 16, 2009.

ordinance requires compliance with the applicable LEED® performance standards for New Construction, Version 2.2, criteria SS6.1 and SS6.2 for stormwater management, as well as the BMPs and Stormwater Design Guidelines of the SFPUC (1304C.0.3). Additionally, for high-rise residential buildings (1304C.1.3), new group B and M occupancy buildings (1304C.2), and new large commercial buildings (1304C.2.2),water efficient landscaping (LEED® WE1.1) and water conservation are required (LEED® WE3.2).

LEED® SS6.2 addresses stormwater management and has been adopted by the San Francisco Stormwater Design Guidelines for MS4s. The stormwater management program seeks to reduce impervious cover, promote infiltration, and capture and treat 90 percent of the runoff from an average annual rainfall event (for semi-arid watersheds; in San Francisco, treatment of 90 percent is interpreted as treating runoff produced by a rain event generating 0.75 inches) using acceptable BMPs. In addition, BMPs used to treat runoff must be capable of removing 80 percent of the average annual post-development total suspended solid load contained in stormwater runoff. The BMPs are considered to meet these criteria if (1) they are designed in accordance with standards and specifications from a state or local program that has adopted these performance standards, or (2) there are filed performance monitoring data that demonstrate compliance with the criteria. LEED® WE1.1 addresses water efficient landscaping. Permit applicants must submit documentation verifying a minimum of 50 percent reduction in use of potable water for landscaping (compared to the mid-summer baseline case). LEED® WE3.2 addresses water use reduction. Permit applicants must submit documentation demonstrating achievement of a minimum 20 percent reduction in the use of potable water. Effective January 1, 2011, the required reduction in use of water is 30 percent (compared to the water use baseline calculated for the building [not including irrigation] after meeting the USEPA Energy Policy Act of 1992 requirements).[560] Although not specified in the Green Building ordinance, for the purposes of the project it was assumed that the reduction would be compared to the Maximum Applied Water Allowance established in the pending California Water Efficient Landscape Ordinance.[561]

City of San Francisco Codes

Storm Drain System Design Criteria

San Francisco Subdivision Regulations. In 1982, the San Francisco Bureau of Engineering prepared the San Francisco Subdivision Regulations, general guidelines for the planning and improvement of subdivided lands, pursuant to Section 1311 of the *San Francisco Subdivision Code*. Chapters IV, XIII, and XIV of the Subdivision Regulations contain standards pertaining to the design and capacity of storm sewer systems.

HPS Stormwater Design Guidelines. The SFPUC has prepared stormwater design standards for HPS referred to as the Design Criteria and Standards, Combined Sewer, Separate Sanitary and Storm Systems, and Upstream Stormwater Management Systems, Hunters Point Shipyard (HPS Stormwater Design Guidelines). These provisions currently apply to HPS through the HPS Subdivision process and it is anticipated that the HPS Subdivision Code will be amended to include Candlestick Point. In accordance with these regulations, and for both HPS Phase II and Candlestick Point storm drain systems, the specific design criteria are:

---

[560] The Energy Policy Act of 1992 set goals, created mandates, and amended utility laws to increase clean energy use and improve overall energy efficiency in the United States. The Act consists of twenty-seven titles detailing various measures designed to lessen the nation's dependence on imported energy, provide incentives for clean and renewable energy, and promote energy conservation in buildings.

[561] Arup, Candlestick Point / Hunters Point Shipyard Phase II Water Demand Memorandum, October 15, 2009.

- Piped storm drain systems designed for stormwater runoff from up to the 5-year storm event when flowing full or surcharged.
- Flow from the 5-year storm event up to the 100-year storm event conveyed in streets and drainage channel rights-of-way.

Public Works Code, Article 4.1

In compliance with the Municipal NPDES Permit, Article 4.1 (Section 123) of the *San Francisco Public Works Code*, the City requires that all dischargers must comply with all state and federal orders issued to the City including all of the City's NPDES permits. The *Public Works Code* also prohibits the discharge of hazardous waste (including stormwater runoff) and other pollutants that would violate the City's federal and state discharge permits. The following are specific provisions of Article 4.1 that apply to construction activities:

- **Construction Requirements for Areas Served by the Combined Sewer System.** For construction sites served by the combined sewer system, the City requires the development and implementation of a SWPPP, which includes an Erosion and Sediment Control Plan (ESCP), and compliance with the City's Construction Site Water Pollution Prevention Program, to reduce the impacts of construction site runoff. The SWPPP must be submitted to the SFPUC prior to the initiation of construction. The SFPUC conducts periodic inspections to ensure compliance with the SWPPP. Article 4.1 of the *San Francisco Public Works Code* also regulates the quantity and quality wastewater discharges (such as dewatering from construction sites) to the combined sewer system.
- **Construction Requirements for Areas Served by the Separate Sewer System.** For separate sewer systems, Article 4.1 requires compliance with applicable NPDES permits, including compliance with the Construction General Permit and preparation and implementation of a SWPPP, compliance with the SWMP, and compliance with the City's Construction Site Runoff Water Pollution Prevention Program, including implementation of erosion and sediment control BMPs.
- **Dewatering Discharges to the Combined Sewer System.** Discharges of temporary dewatering from construction sites to the combined sewer system are regulated by a Batch Wastewater Discharge permit issued by the SFPUC, under Article 4.1 of the *San Francisco Public Works Code*. As such, the Project Applicant must obtain a Batch Wastewater Discharge permit from the SFPUC prior to the beginning of groundwater dewatering to the combined sewer system. Specific permit terms and conditions are imposed by the SFPUC to maintain SFPUC's compliance with its own Wastewater Discharge Permit issued by the SFRWQCB. Under the Batch Wastewater Discharge permit, the discharge must meet specific numeric effluent limitations for toxic and conventional pollutants, and monitoring is required to ensure compliance.

San Francisco Stormwater Design Guidelines

The City, the SFPUC, and the Port have jointly developed the *Draft San Francisco Stormwater Design Guidelines* (Stormwater Design Guidelines)[562] that describe the planning, engineering, and regulatory framework for designing post-construction stormwater controls at the parcel level in the separate storm sewer areas in San Francisco. When finalized, the Stormwater Design Guidelines[563] are anticipated to apply to all projects greater than 5,000 square feet, and projects in areas subject to San Francisco's Green Building Ordinance.

[562] City of San Francisco, San Francisco Public Utilities Commission, and Port of San Francisco, 2009, o*p. cit.*
[563] Draft Stormwater Design Guidelines were released in February 2009[563] and are expected to be adopted by the end of 2009.

The Guidelines require applicants for new and redevelopment projects to prepare a Stormwater Control Plan (SCP) that demonstrates how the project will:

- Capture and treat a precipitation depth of 0.75 inch using volume-based BMPs (LEED® SS6.2) or
- Capture and treat a rainfall intensity of 0.2 inch per hour using flow-based BMPs

The SCP also requires inclusion of source control BMPs for the following portions of a development: 100,000 square foot commercial development, restaurants, retail gasoline outlets, automotive repair shops, and parking lots. The SCP requires development of an Operations and Maintenance Plan that identifies responsible parties, funding sources, maintenance activities and schedules for all BMPs.

Floodplain Management Program

FEMA Floodplain Management Program

The NFIP was created to provide financial backing for affordable flood insurance in exchange for the adoption of floodplain management regulations by communities participating in the program. On March 28, 2008, the San Francisco Board of Supervisors adopted Resolution No. 352-08, authorizing the City's enrollment in the NFIP. As a requirement for joining the NFIP, the City must adopt and enforce a floodplain management ordinance that governs new construction and substantial improvements to existing buildings in flood-prone areas. San Francisco subsequently adopted Ordinance No. 188-08 establishing a floodplain management program, and the interim controls in this ordinance will remain in place until FEMA has published the final FIRM for San Francisco, at which time San Francisco will adopt permanent controls for floodplain management. In July 2008, the City released Interim Floodplain Maps to implement the City's floodplain management ordinance until the final FIRMs are released by FEMA.

The NFIP regulations allow a local jurisdiction to issue variances to its floodplain management ordinance under certain narrow circumstances, without jeopardizing the local jurisdiction's eligibility in the NFIP. However, the particular projects that are granted variances by the local jurisdiction may be deemed ineligible for federally backed flood insurance by FEMA. In correspondence between the Office of the City Administrator and FEMA dated July 11, 2008,[564] the City advised FEMA of its intention to issue a variance in the permanent floodplain management controls to address the requirements for new construction and substantial improvements to structures on piers in coastal high hazard areas (V-Zones).[565] NFIP regulations prohibit construction seaward of mean high tide in a V-Zone, however, the City will develop engineering controls to ensure that structures built in or over the water can be constructed to withstand a 100-year flood if:

- The pier deck of the structure is above the 100-year elevation
- Companion engineering analysis of the structure demonstrates its ability to withstand lateral forces generated by a 100-year flood

[564] Linda Yeung, Deputy City Administrator, City and County of San Francisco Office of the City Administrator, letter to Gregory Blackburn, FEMA Region IX, July 11, 2008.
[565] Note that FEMA refers to these zones as both V-Zones and Zone V.

Although resolution of this issue with FEMA is pending, development within the Project site would be subject to the interim controls in the floodplain management program, unless alternative requirements are adopted prior to the issuance of building permits.

City of San Francisco

In August, 2008, the City of San Francisco adopted an ordinance establishing a floodplain management program (Article XX, Sections 2A.280 through 2A.285 of the *San Francisco Administrative Code*), designating the City Administrator as the floodplain administrator and providing requirements for designating floodplains and for construction and development in floodplains.

Development in a floodplain or flood-prone area, as designated by the Floodplain Administrator, requires a permit and demonstrated compliance with the floodplain management standards. Article XX, Sections 2A.280 through 2A.285 require that all new construction and substantial improvements in designated flood prone areas shall:

- Be designed (or modified) and adequately anchored to prevent flotation, collapse, or lateral movement of the structure resulting from hydrodynamic and hydrostatic loads, including the effects of buoyancy
- Be constructed with materials and utility equipment resistant to flood damage and using methods and practices that minimize flood damage
- Include electrical, heating, ventilation, plumbing and air conditioning equipment and other service facilities that are designed and/or located so as to prevent water from entering or accumulating within the components during conditions of flooding

The ordinance requires that subdivision proposals in flood-prone areas be reviewed to ensure that:

- All such proposals are consistent with the need to minimize flood damage within the flood-prone area
- All public utilities and facilities such as sewer, gas, electrical, and water systems are located and constructed to minimize or eliminate flood damage
- Adequate drainage is provided to reduce exposure to flood hazards

All new and replacement water supply and sanitary sewage systems must be designed to minimize or eliminate infiltration of flood waters into the systems, and discharges from systems into flood waters.

The Chief Harbor Engineer of the Port of San Francisco and the City Floodplain Administrator are required to consult and coordinate with FEMA to create appropriate building standards for developing any finger piers in flood prone areas within the Port's jurisdiction. The floodplain management regulations in this ordinance are consistent with the NFIP requirements for communities like San Francisco, where FEMA is in the process of preparing, but has not completed a final FIRM. When FEMA issues a final FIRM designating SFHAs in San Francisco, NFIP regulations require that the adopted floodplain management program be reviewed and modified by the City to ensure consistency with NFIP requirements applicable to FEMA-mapped communities.

III.M.4 Impacts

Significance Criteria

The CCSF and Agency have not formally adopted significance standards for impacts related to hydrology and water quality, but generally consider that implementation of the Project would have significant impacts if it were to:

- M.a Violate any water quality standards or waste discharge requirements
- M.b Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate (e.g., the production rate of pre-existing nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted)
- M.c Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on site or off site
- M.d Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on site or off site
- M.e Create or contribute runoff water that would exceed the capacity of existing or planned storm sewer systems or provide substantial additional sources of polluted runoff
- M.f Otherwise substantially degrade water quality
- M.g Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map
- M.h Place within a 100-year flood hazard area structures that would impede or redirect flood flows
- M.i Expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam
- M.j Expose people or structures to inundation by seiche, tsunami, or mudflow

Analytic Method

Hydrology and water quality would be affected by the amount of impervious surfaces, the introduction of new pollutants, migration of existing pollutants, and sea level rise. As described in Chapter II (Project Description), the Project would result in the demolition of existing surface improvements, reflective of past land uses within Candlestick Point and HPS Phase II, and the creation of new land uses, which could affect water quality in the Lower Bay. The focus of the hydrology and water quality analysis is on those portions of the Project site that would be subject to development, and both construction and operational impacts are addressed in this section. Criteria for evaluating effects on surface and groundwater quality in the San Francisco Bay Area are based on water quality standards established in the Basin Plan, including TMDLs, and whether the Project could cause or contribute to water quality degradation.

Additionally, Project impacts are assessed in light of existing regulatory requirements that would serve to mitigate potential impacts. The effectiveness of existing regulations to mitigate potential impacts is often affected by discretionary requirements, site characteristics or project features not yet detailed, and design-

level considerations. Because there is some discretion in how these regulations are applied, they are presented as mitigation measures to outline the specific process by which the Project will comply with these regulations.

Under the Project, existing improvements and impervious surfaces would be replaced with new structures and infrastructure, including roads, parking areas, and utilities. This would generally result in the replacement of impervious surfaces, because much of the area subject to development is already occupied by existing buildings and other impervious surfaces. The installation of new impervious surfaces and changes in site drainage patterns could increase the rate and amount of stormwater runoff from the Project site. Identification of impervious cover involved an analysis, using available Geographic Information Systems (GIS) data of existing land uses, to estimate the extent of coverage by existing structures, roads, parking lots, and other impervious surfaces. Site plans for the Project were analyzed to determine the extent of future impervious cover for the proposed future uses.

Stormwater Runoff

Potential Project operational effects on the amount of stormwater runoff were estimated based on Project changes in surface runoff characteristics, as affected by the amount of impervious surfaces, the time it would take runoff to travel to the storm drain system or directly to the Lower Bay, and precipitation records. Details of the stormwater runoff and pollutant load analysis are presented in Appendix M1. The construction and development of new land uses, compared to existing land uses and new or replaced infrastructure, could result in the introduction of various pollutants into stormwater runoff. Thus, the analysis also estimates the potential for an increase in runoff to occur and whether the introduction of new land uses would result in adverse impacts to water quality. At this time, runoff volumes and rates can only be estimated because the precise mix, size, and routing of stormwater BMPs that would be used to collect, treat, infiltrate, and discharge runoff have not been identified; the type of BMPs, their locations, and sizes could all affect stormwater flow by detention and retention.[566] Therefore, the runoff estimates do not include BMPs.

Stormwater Quality

Potential Project effects on water quality are estimated based on Project changes in land use and site runoff characteristics and reported literature values for pollutant concentrations in runoff from land use categories for some of the identified the constituents of concern (COCs). Annual pollutant loads for chemical constituents were estimated as a product of annual runoff volume and typical values for pollutant concentrations in stormwater runoff as a function of land use. As such, an increase in stormwater runoff would result in an increase in pollutant load, if expected pollutant concentrations in stormwater runoff from varying land uses remains the same or similar. Conversely, a reduction in stormwater runoff can still result in an increase in pollutant load if the concentration of the pollutant in stormwater runoff is expected to increase substantially. This calculation of pollutant loading provides an estimate of the relative amount (i.e., total pounds) of pollutant that would enter the receiving water during an average year. Not all COCs are included in the pollutant load analysis because sufficient data is not available. Details of the stormwater runoff and pollutant load analysis are presented in Appendix M1.

[566] Detention refers to slowing down, temporary storing, and releasing stormwater runoff at a controlled rate. Retention refers to capturing stormwater runoff and preventing discharge from the detention device. Retention can be accomplished by storage or infiltration.

Surface Water Constituents of Concern

Surface water COCs for the Project would include those pollutants likely to be present in stormwater runoff from the Project site and those for which the receiving water(s) (Lower Bay, Candlestick cove) are listed as impaired or for which there is an existing TMDL. COCs also include the pollutants of concern targeted by the SWMP, prepared in compliance with the Municipal Stormwater General Permit: suspended solids (sediments), litter, heavy metals, and petroleum hydrocarbons. Additionally, the potential for the Project to transport existing contaminants to surface waters are addressed in this impacts analysis. Table III.M-2 (Pollutants Likely to Be Present in Stormwater Runoff from Project Land Uses) lists the potential pollutants in stormwater runoff from the Project. Consequently, the Project COCs include sediment, nutrients, pesticides, oil and grease, metals (including mercury), trash and debris, pathogens, organic compounds (including PCBs), and oxygen-demanding substances and are described below.

- **Bacteria and Viruses (Pathogens).** Bacteria and viruses are common contaminants in stormwater. For separate storm drain systems, sources may include animal excrement and sanitary sewer overflow. High levels of indicator bacteria in stormwater have led to closures of water bodies to contact recreation such as swimming. Pathogens are not listed on the 303(d) list as impairing the water quality of the Lower Bay.
- **Metals.** Emissions from automobiles and many artificial surfaces of the urban environment (e.g., those covered with galvanized metal, paint, or preserved wood), contain metals, which enter stormwater as the surfaces corrode, flake, dissolve, decay, or leach. Metals are often associated with sediments in stormwater. Metals are of concern because they are toxic to aquatic organisms and can bioaccumulate (accumulate to toxic levels in aquatic animals such as fish, which can be a health hazard if consumed by other aquatic organisms or people). Mercury is a metal listed on the 303(d) list as impairing the water quality of the Lower Bay.

  Mercury in particular is a pollutant of concern in the Lower Bay and is the subject of a TMDL. Sources of mercury in urban runoff include mercury-containing instruments, switches and thermostats, and fluorescent lighting.[567]
- **Nutrients.** Nutrients including nitrogen and phosphorous are the major plant nutrients used for fertilizing landscapes, and are often found in stormwater. The discharge of nutrients into water bodies can cause excessive aquatic algae and plant growth (i.e., eutrophication) resulting in water body impairment. Nutrients are not listed on the 303(d) list as impairing the water quality of the Lower Bay.
- **Sediment.** Sediment is a common component of stormwater, and can be a pollutant. Sediment can be detrimental to aquatic life by interfering with photosynthesis, respiration, growth, reproduction, and oxygen exchange in water bodies. Sediment can transport other pollutants that are attached to it such as nutrients, trace metals, pesticides, and petroleum hydrocarbons. Sediments are not listed on the 303(d) list as impairing the water quality of the Lower Bay.

X = Expected pollutant; P = Potential pollutant; a blank cell indicates the pollutant is neither an expected nor a potential pollutant

a. A potential pollutant if landscaping exists on site
b. A potential pollutant if the site includes uncovered parking areas
c. A potential pollutant if land use involves food or animal waste products
d. Including petroleum hydrocarbons
e. Including solvents

- **Trash and Debris.** Trash (such as paper, plastic, polystyrene packing foam, and aluminum materials) and debris (biodegradable organic matter such as leaves, grass cuttings, and food waste) are general waste products on the landscape. The presence of trash and debris may have a significant impact on the recreational value of a water body and aquatic habitat. Excess organic matter can create a high oxygen demand in a water body causing degradation of water quality. In addition, in areas where stagnant water exists, the presence of excess organic matter can promote septic conditions resulting in the growth of undesirable organisms and the release of odorous and hazardous compounds such as hydrogen sulfide. Trash and debris are not listed on the 303(d) list as impairing the water quality of the Lower Bay.
- **Oxygen-Demanding Substances.** Oxygen-demanding substances include biodegradable organic material as well as chemicals that react with dissolved oxygen in water to form other compounds. For example, food and pet wastes are oxygen-demanding substances. The oxygen demand of a substance can reduce the dissolved oxygen concentration of a water body and cause impairment such as fish kills. Oxygen-demanding substances are not listed on the 303(d) list as impairing the water quality of the Lower Bay.
- **Oil and Grease.** Oil and grease includes a wide array of hydrocarbon compounds, some of which are toxic to aquatic organisms at low concentrations. Sources of oil and grease include leakage, spills, cleaning and sloughing associated with vehicle and equipment engines and suspensions, leaking and breaks in hydraulic systems, improper disposal of cooking oils/fats at restaurants, and improper waste oil disposal. Oil and grease are not listed on the 303(d) list as impairing water quality of the Lower Bay.
- **Pesticides.** Pesticides (including herbicides, fungicides, rodenticides, and insecticides) have been repeatedly detected in stormwater at toxic levels, even when pesticides have been applied in accordance with label instructions. Pyrethroids, which are an emerging class of pesticide that is a primary replacement for pesticides recently phased out from urban use by USEPA (diazinon and chlorpyrifos), have been demonstrated to be toxic to organisms dwelling in the shallow sediments of California's surface water bodies; and it has been shown that toxicity is more severe and widespread in urban areas than in agricultural areas. The likely sources of the pyrethroids causing the identified toxicity are pest control applications around buildings and to a lesser extent, applications

on lawns and gardens. Legacy pesticides (e.g., chlordane, dieldrin, and DDT) are listed on the 303(d) list as impairing water quality of the Lower Bay.

- **Organic Compounds.** Organic compounds may be found in stormwater at concentrations that may be toxic to aquatic organisms. Man-made organic compounds (e.g., adhesives, cleaners, sealants, solvents) are widely applied, may be improperly stored and disposed, and come into contact with stormwater. In addition, illegal and deliberate dumping of these chemicals into storm drains and inlets causes environmental harm to waterways. Polychlorinated biphenyls (PCBs), dioxins, and furans are listed on the 303(d) list as causing impairing water quality of the Lower Bay.

  PCBs are specific pollutants of concern at the Project site because of the pending TMDL. PCBs were manufactured in the United States between 1929 and 1977 for a variety of uses, until USEPA banned the manufacture and distribution of materials containing detectable PCBs in 1984.[568,569] Therefore, PCB contamination often originates in older sites and materials (e.g., building caulk).[570] However, PCBs are still in use to some extent today (e.g., in transformers) and the potential for continued PCB releases into the environment remains.[571] PCBs in sediment originating from contaminated areas can come into contact with urban runoff and may be discharged into receiving waters.

Groundwater Constituents of Concern

COCs for groundwater quality are those chemicals that could rapidly reach the groundwater aquifer via infiltration of stormwater runoff, as well as those constituents that DWR indicates are elevated in local groundwater. The potential for residual contamination to mobilize and migrate as a result of implementation of the Project is addressed in this impacts analysis. Constituents in stormwater runoff that could infiltrate into groundwater are mobile constituents that would not be filtered or bound by soils located above the groundwater table. These constituents include total dissolved solids (measures the dissolved content of water including many constituents that are mobile), chloride, and nitrate. Nitrate and chloride are also groundwater COCs because DWR has indicated local groundwater may have elevated concentrations of these constituents. Total dissolved solids (TDS), chloride, and nitrate are described below.

- **Total Dissolved Solids.** Total dissolved solids (TDS) are commonly referred to as "salts," although metals and other dissolved solids can contribute to TDS concentrations. The source of salts (including nutrients) are the water soluble inorganic and organic constituents in imported water, soil materials/minerals, animal wastes, fertilizers and other soil amendments, land use, and industrial

wastes.[572] Water with a TDS above 500 mg/l is not recommended for use as drinking water (EPA secondary drinking water guidelines) and water with a TDS above 1,500 to 2,600 mg/l is generally considered problematic for irrigation use on crops with low or medium salt tolerance. [573] An elevated TDS concentration also indicates that groundwater may contain elevated levels of ions that are above the Primary or Secondary Drinking Water Standards, such as an elevated level of nitrate, arsenic, aluminum, copper, lead, and others.[574]

- **Chloride.** Sources of chloride could include seawater intrusion, thermal water, and dissolved minerals from marine and volcanic rocks.[575] Large concentrations of chloride can make water unusable for drinking and can also be toxic to plants.[576]
- **Nitrate.** The major sources of nitrates in urban groundwater are mostly related to wastewater disposal (including leaky sewers) and solid waste disposal.[577] Groundwater contamination by nitrate can occur as a result of sewage infiltration, water supply leakage, contaminated land, and highway and urban runoff.[578] High nitrate concentrations can cause methemoglobinemia (a blood disease) in infants.[579]

Flood Hazards

Criteria for evaluating flooding hazards are based on SFPUC stormwater drainage system design criteria and the proposed 100-year flood zones as established by FEMA and the City Administrator's Interim Floodplain Maps. Although a Base Flood Elevation has not been formally adopted for the Project site, the Base Flood Elevation was estimated by Moffatt and Nichol for this analysis.[580] In addition to the potential for the Project to increase runoff and cause or contribute to on- or off-site flooding hazards, given the proximity of the Project site to the Bay, the analysis also considers the potential for development to result in flooding hazards associated with a rise in sea level. These features would be designed to protect development at HPS Phase II from existing coastal flooding in addition to a rise in sea level of up to 16 inches with a development setback to allow any future increases in elevation to accommodate higher SLR values, should they occur.

Cumulative Impacts

The Project's potential contribution to cumulative hydrology and water quality impacts are also evaluated in the context of past, present, and reasonably foreseeable future development expected to occur in the Project vicinity.

Construction Impacts

Impact HY–1: Water Quality Standards and Waste Discharge Requirements

Impact of Candlestick Point

This discussion addresses whether the Project could result in a violation of either water quality standards or waste discharge requirements. As previously mentioned, the CWA requires each state to adopt water quality standards for receiving water bodies and to have those standards approved by the USEPA. Water quality standards consist of designated beneficial uses for a particular receiving water body (e.g. wildlife habitat, agricultural supply, fishing etc.), along with water quality objectives necessary to support those uses. Discharges from the combined sewer system are regulated under two individual National Pollutant Discharge Elimination System (NPDES) permits issued by the SFRWQCB that identify specific waste discharge requirements (WDRs). The SFRWQCB incorporates conditions into WDRs to be protective of water quality and comply with water quality standards.[581] In some places in this section, the WDRs contained in the NPDES permits issued by the SFRWQCB are also referred to as Waste Discharge Permits.

In addition, a key policy of California's water quality program is the State's Antidegradation Policy. This policy, formally known as the Statement of Policy with Respect to Maintaining High Quality Waters in California (SWRCB Resolution No. 68-16), restricts degradation of surface and ground waters. In particular, this policy protects water bodies where existing quality is higher than necessary for the protection of beneficial uses. Under the Antidegradation Policy, any actions that can adversely affect water quality in all surface and ground waters must: (1) be consistent with maximum benefit to the people of the State; (2) not unreasonably affect present and anticipated beneficial use of the water; and (3) not result in water quality less than that prescribed in water quality plans and policies, (i.e., will not result in exceedances of water quality objectives).[582]

Impact HY–1a **Construction at Candlestick Point would not cause an exceedance of water quality standards or contribute to or cause a violation of waste discharge requirements. (Less than Significant with Mitigation)** ***[Criterion M.a]***

The discharge of sediment-laden runoff, groundwater from temporary construction dewatering activities, the incidental or accidental release of construction materials or products into the combined sewer system, separate storm sewer systems, or directly to receiving waters within or adjacent to the Project site, or the exposure of surface water or groundwater to contaminated soils could impair water quality.

[581] California Regional Water Quality Control Board San Francisco Bay Region, 2008, Order No. R2-2008-007 and NPDES No. CA0037664.
[582] SWRCB, 1968, Statement of Policy with Respect to Maintaining High Quality of Waters in California. Resolution No. 68-16.

Construction activities within Candlestick Point would include demolition of existing facilities, the clearing and grading of development areas (including excavation, trenching, movement of soil, and the importation of fill soils), and the subsequent construction of new facilities and associated infrastructure. Construction activities would expose soils to rainfall and runoff, construction vehicle traffic, and wind, which could result in the erosion of soils and the mobilization and deposition of dust from disturbed development areas.

Construction activities could also result in the incidental release of construction materials or the accidental spill of substances commonly used in construction (e.g., paints, solvents, petroleum products, equipment leakage, and others). The incidental release or accidental spill of such substances could result in the introduction of those substances directly to the Lower Bay, or into stormwater runoff that would subsequently discharge into the combined or separate sewer system.

Construction activities could also disturb contaminated soils and increase their exposure to surface water runoff and cause or contribute to surface water or groundwater quality degradation. Historic land uses within Candlestick Point may have resulted in the contamination of soil or groundwater by hazardous materials. Although the potential for residual hazardous materials to occur at Candlestick Point is not high, portions of Candlestick Point (bayward from the high tide mark) are primarily fill material and could, therefore, contain a variety of contaminants; in addition, unknown contamination may also be present. The potential for such contamination to be encountered during construction is addressed in Section III.K. Mitigation measures MM HZ-1a (Article 22 Site Mitigation Plan), MM HZ-2a.1 (Unknown Contaminant Contingency Plan), MM HZ-15 (Asbestos Dust Control Plan) would reduce the potential for hazardous materials that may be present in soils to be mobilized as pollutants in stormwater runoff as a result of construction activities.

Construction of the Project would require excavation of portions of the site for building foundations, basements, utilities, or mechanical equipment that may be installed below grade. Excavation and grading could encounter groundwater, which has generally been found at locations between 10 and 15 feet below the ground surface. Historically, depths to groundwater have been measured at depths as shallow as three feet in the lowland areas, and as deep as 30 feet bgs in the upland areas.[583] The installation of below-grade building elements could, therefore, require temporary dewatering and the short-term discharge of groundwater to either the combined sewer system or separate storm sewer systems.

As previously discussed, portions of Candlestick Point drain to the combined sewer system, while other portions discharge directly to the Lower Bay or drain to separate sewer systems that then drain to the Lower Bay. Construction activities could result in construction-related discharges to the combined sewer system, separate sewer systems, sheet flow to the Lower Bay, or direct discharges to surface waters. The combined sewer system collects and treats stormwater flows prior to discharge to the Lower Bay; however, there is currently no treatment of stormwater runoff that drains to the Lower Bay via direct discharges or separate sewer systems.

[583] PRC, et al., *Parcel E Remediation Investigation Draft Report, Hunters Point Shipyard, San Francisco, CA*, 1997, Part of Comprehensive Long Term Environmental Action Navy (Clean II).

Combined Sewer System

Erosion and Sediment Control

Construction-related discharges to the combined system would be subject to the City's Construction Site Runoff Pollution Prevention Program requirements that are described in the City's Construction Site Water Pollution Prevention Program. The City's Construction Site Runoff Pollution Prevention Procedures were established to ensure that all businesses comply with all appropriate stormwater laws and other City requirements, and includes inspection of construction sites to ensure compliance. Under this program, all construction sites must prepare a SWPPP, which includes an ESCP. The SWPPP must be submitted to the City and include BMPs that prevent illicit discharge into the combined sewer system. The City conducts periodic inspections to ensure compliance with the SWPPP, thereby reducing the potential for pollutants in stormwater runoff to enter the combined sewer system and cause or contribute to violation of the SWPCP Wastewater Discharge Permit. The SWPPP is a design-phase document that would depend on site specific conditions, final grading plans, staging areas, topography, and other conditions. As such, preparation of an SWPPP allows for discretionary selection of many BMPs and plan elements by the Project Applicant.

The construction BMPs contained in the SWPPP shall be implemented to prevent transport of sediment and residual contaminants to the combined sewer system or Lower Bay. Perimeter protection would minimize transport of sediment off-site or into the combined sewer system. Materials and waste handling BMPs prevent spills, contact of rainwater with pollutants, and provide for quick and effective clean up in the event of a spill. These BMPs would reduce the potential for sediment and pollutants to enter the combined sewer system in a manner that would exceed water quality standards or cause or contribute to a violation of the applicable WDRs.

To reduce construction-related pollutants in stormwater runoff, the following mitigation measure shall be implemented:

MM HY-1a.1 *Storm Water Pollution Prevention Plan: Combined Storm Sewer System. In compliance with the Article 4.1 of the Public Works Code and the City's Construction Site Water Pollution Prevention Program, the Project Applicant shall submit a site-specific Storm Water Pollution Prevention Plan (SWPPP) to the SFPUC for approval, prior to initiating construction activities in areas draining to the combined sewer system. The SFPUC requires implementation of appropriate Best Management Practices (BMPs) from the California Stormwater Quality Association Stormwater BMP Handbook-Construction[584] or the Caltrans Construction Site BMPs Manual.585 In accordance with SFPUC's requirements, the SWPPP shall include:*

- *An Erosion and Sediment Control Plan that includes a site map illustrating the BMPs that will be used to minimize on-site erosion and the sediment discharge into the combined sewer system, and a narrative description of those BMPs. Appropriate BMPs for Erosion and Sediment Control Plan may include:*
  - *Scheduling—Develop a schedule that includes sequencing of construction activities with the implementation of appropriate BMPs. Perform construction activities and control practices in*

[584] California Stormwater Quality Association, 2003, *Stormwater BMP Handbook- Construction*, January 2003 with revisions through 2004.
[585] Caltrans, 2003, *Caltrans Stormwater Quality Handbook Construction Site Best Management Practices Manual*, March 1, 2003.

accordance with the planned schedule. Schedule work to minimize soil-disturbing activities during the rainy season. Schedule major grading operations for the dry season when practical. Monitor the weather forecast for rainfall and adjust the schedule as appropriate.

- > *Erosion Control BMPs—Preserve existing vegetation where feasible, apply mulch or hydroseed areas with native, non-invasive species, until permanent stabilization is established, and use soil binders, geotextiles and mats, earth dikes and drainage swales, velocity dissipation devices, slope drains, or polyacrylamide to protect soil from erosion.*
- > *Wind Erosion BMPs—Apply water or other dust palliatives to prevent dust nuisance; prevent overwatering which can cause erosion. Alternatively, cover small stockpiles or areas that remain inactive for seven or more days.*
- > *Sediment Control BMPs—Install silt fences, sediment basins, sediment traps, check dams, fiber rolls, sand or gravel bag barriers, straw bale barriers, approved chemical treatment, and storm drain inlet protection to minimize the discharge of sediment. Employ street sweeping to remove sediment from streets.*
- > *Tracking Controls—Stabilize the construction site entrance to prevent tracking of sediment onto public roads by construction vehicles. Stabilize on-site vehicle transportation routes immediately after grading to prevent erosion and control dust. Install a tire wash area to remove sediment from tires and under carriages.*

- *Non-Stormwater Management BMPs that may include water conservation practices; dewatering practices that minimize sediment discharges; and BMPs for: paving and grinding activities; identifying illicit connections and illegal dumping; irrigation and other planned or unplanned discharges of potable water; vehicle and equipment cleaning, fueling, and maintenance; concrete curing and finishing; temporary batch plants; implementing shoreline improvements and working over water. Discharges from dewatering activities shall comply with the SFPUC's Batch Wastewater Discharge Requirements that regulate influent concentrations for various constituents.*
- *Waste Management BMPs shall be implemented for material delivery, use, and storage; stockpile management; spill prevention and control; solid and liquid waste management; hazardous waste management; contaminated soil management; concrete waste management; and septic/sanitary waste management.*
- *SWPPP Training Requirements—Construction personnel will receive training on the SWPPP and BMP implementation.*
- *Site Inspections and BMP Maintenance—An inspector identified in the SWPPP will inspect the site on a regular basis, before and after a storm event, and once each 24-hour period during extended storms to identify BMP effectiveness and implement corrective actions if required. The SWPPP shall include checklists that document when the inspections occurred, the results of the inspection, required corrective measures, and when corrective measures were implemented. Required BMP maintenance related to a storm event shall be completed within 48 hours of the storm event.*

Groundwater Dewatering

For construction activities that discharge to the combined system, discharge of groundwater from temporary construction dewatering activities would be regulated under Article 4.1 of the *San Francisco Public Works Code*, which prohibits the discharge of hazardous waste and other pollutants that violate the City's federal and state NPDES permits. As previously mentioned, these NPDES Permits establish the waste discharge requirements for the combined sewer system.

Pursuant to Article 4.1 of the *San Francisco Public Works Code*, discharges of dewatering water to the combined sewer system would also be regulated under a Batch Wastewater Discharge permit that would be requested by the Applicant and issued by the SFPUC. Specific permit terms and conditions are imposed by the SFPUC to maintain SFPUC's compliance with its own Wastewater Discharge Permit issued by the SFRWQCB. Under the Batch Wastewater Discharge permit, the discharge must meet specific numeric effluent limitations for toxic and conventional pollutants and monitoring is required to ensure compliance.[586]

Summary (Combined Sewer System)

With respect to erosion and sediment control, implementation of mitigation measures MM HY-1a.1 (Stormwater Pollution Prevention Plan and Erosion and Sediment Control Plan), MM HZ-1a (Article 22 Site Mitigation Plan), and MM HZ-2a.1 (Unknown Contaminant Contingency Plan) would reduce the potential for contaminants, sediments, or pollutants in stormwater runoff to enter the combined sewer system. Compliance with Article 4.1, including regulation under SFPUC's Batch Wastewater Discharge permit, would reduce the potential for pollutant discharges caused by groundwater dewatering to enter the combined sewer system. Water quality standards would not be exceeded nor would the Project cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Separate Storm Sewer System

Erosion and Sediment Control

In areas that drain to a separate storm sewer system, construction runoff would not be treated in the sanitary sewer system. In these areas, or in areas that discharge runoff directly to the Bay (such as sheet flow from the CPSRA), the Project Applicant would be required to comply with the state's Construction General Permit, including development, implementation, and submittal of a SWPPP (which is required by mitigation measure MM HY-1a.2) that includes minimum BMP requirements, depending upon the Risk Level determination in accordance with the Construction General Permit.

The Construction General Permit specifies a risk-based permitting approach based on the potential for the project to cause or contribute to sedimentation of the receiving water (in this case, the Lower Bay), as well as the sensitivity of the receiving water to sedimentation. It contains numeric action levels (moderate risk, Risk Level 2) and effluent limitations (high risk, Risk Level 3) for pH and turbidity. The Construction General Permit also requires effluent and receiving water (only for some Risk Level 3 sites) monitoring to demonstrate compliance with permit requirements, and corrective action must be taken if these limitations are exceeded or visual observations indicate the presence of pollutants. The results of the monitoring and corrective actions must be reported annually to the SWRCB.

The Construction General Permit requires that the Project Applicant file Permit Registration Documents prior to beginning of construction activities. These documents include a NOI, risk assessment, site map, a SWPPP, annual fee, and signed certification statement. The SWPPP must include measures to ensure that all pollutants and their sources are controlled; non-stormwater discharges are identified and either eliminated, controlled, or treated; site BMPs are effective and result in the reduction or elimination of pollutants in stormwater discharges and authorized non-stormwater discharges; and BMPs installed to

[586] San Francisco Public Utilities Commission, 2008, Requirements for Batch Wastewater Discharges and associated Appendixes, July 10, 2008.

reduce or eliminate pollutants after construction are completed and maintained. The SWPPP must demonstrate that calculations and design details, as well as BMP controls for site run-on, are complete and correct. The Construction General Permit also includes specific minimum BMPs required for stormwater control, based on the risk level determined for the Project site.

The Construction General Permit specifies minimum qualifications for the Qualified SWPPP Developer and Qualified SWPPP Practitioner to ensure that: (1) an appropriate SWPPP is developed; (2) BMPs are correctly installed and inspected; and (3) monitoring and reporting is correctly conducted.

Because the Project site does not discharge to a sediment-sensitive water body, which is defined as a sediment impaired water body or a water body with a beneficial use of cold freshwater habitat, fish spawning, and fish migration, the Project would likely be determined to be either a Risk Level 1 (low) or 2 (moderate) project, depending upon the Project site erosion potential. Therefore, construction in the separate storm sewer system areas would have to implement and incorporate at least Risk Level 1 or 2 minimum requirements into the SWPPP.

Compliance with the requirements of the Construction General Permit would serve to reduce pollutants in construction stormwater runoff from Candlestick Point to the separate storm sewer system and sheet flow to the Lower Bay. While the Construction General Permit contains specific minimum required BMPs, additional, discretionary BMPs could also be identified. Additionally, the SWPPP is an adaptive management tool; the SWPPP must be updated as additional considerations arise and if additional BMPs are required to comply with discharge requirements. The following mitigation measure shall be implemented to reduce construction-related pollutants in stormwater runoff:

MM HY-1a.2 *<u>Stormwater Pollution Prevention Plan: Separate Storm Sewer System.</u> Consistent with the requirements of the SWRCB General Permit for Storm Water Discharges Associated with Construction and Land Disturbing Activities (Construction General Permit), the Project Applicant shall undertake the proposed Project in accordance with a project-specific Storm Water Pollution Prevention Plan (SWPPP) prepared by Qualified SWPPP Developer, who shall consult with California State Parks on those elements of the SWPPP that cover the Candlestick Park State Recreation Area, including selection of best management practices and other SWPPP improvements. The SFRWQCB, the primary agency responsible for protecting water quality within the project area, is responsible for reviewing and ensuring compliance with the SWPPP. This review is based on the Construction General Permit issued by the SWRCB.*

The SWPPP shall include, as applicable, all Best Management Practices (BMPs) required in Attachment C of the Construction General Permit for Risk Level 1 dischargers, Attachment D for Risk Level 2 dischargers, or Attachment E for Risk Level 3 dischargers. In addition, recommended BMPs, subject to review and approval by the SFRWQCB, include the measures listed below. However, the measures themselves may be altered, supplemented, or deleted during the SFRWQCB's review process, since the SFRWQCB has final authority over the terms of the SWPPP.

- *Scheduling:*
  - *To reduce the potential for erosion and sediment discharge, schedule construction to minimize ground disturbance during the rainy season. Schedule major grading operations during the dry season when practical, and allow enough time before rainfall begins to stabilize the soil with vegetation or to install sediment-trapping devices.*
  - *Sequence construction activities to minimize the amount of time that soils remain disturbed.*

- *Stabilize all disturbed soils as soon as possible following the completion of ground disturbing work.*
- *Install erosion and sediment control BMPs prior to the start of any ground-disturbing activities.*

■ *Erosion and Sedimentation:*

- *Preserve existing vegetation in areas where no construction activity is planned or where construction activity will occur at a later date.*
- *Stabilize and re-vegetate disturbed areas as soon as possible after construction with planting, seeding, and/or mulch (e.g., straw or hay, erosion control blankets, hydromulch, or other similar material) except in actively cultivated areas. Planting and seeding shall use native, non-invasive species.*
- *Install silt fences, coir rolls, and other suitable measures around the perimeter of the areas affected by construction and staging areas and around riparian buffers, storm drains, temporary stockpiles, spoil areas, stream channels, swales, down-slope of all exposed soil areas, and in other locations determined necessary to prevent off-site sedimentation.*
- *Install temporary slope breakers during the rainy season on slopes greater than 5 percent where the base of the slope is less than 50 feet from a water body, wetland, or road crossing at spacing intervals required by the SFRWQCB.*
- *Use filter fabric or other appropriate measures to prevent sediment from entering storm drain inlets.*
- *Detain and treat stormwater using sedimentation basins, sediment traps, baker tanks, or other measures to ensure that discharges to receiving waters meet applicable water quality objectives.*
- *Install check dams, where applicable, to reduce flow velocities. Check dams reduce erosion and allow sediment to settle out of runoff.*
- *Install outlet protection/energy dissipation, where applicable, to prevent scour of the soil caused by concentrated high velocity flows.*
- *Implement control measures such as spraying water or other dust palliatives to alleviate nuisance caused by dust.*

■ *Groundwater/Dewatering:*

- *Prepare a dewatering plan prior to excavation specifying methods of water collection, transport, treatment, and discharge of all water produced by construction site dewatering.*
- *Impound water produced by dewatering in sediment retention basins or other holding facilities to settle the solids and provide other treatment as necessary prior to discharge to receiving waters. Locate sedimentation basins and other retention and treatment facilities away from waterways to prevent sediment-laden water from reaching streams.*
- *Control discharges of water produced by dewatering to prevent erosion.*
- *If contaminated groundwater is encountered, contact the SFRWQCB for appropriate disposal options. Depending on the constituents of concern, such discharges may be disallowed altogether, or require regulation under a separate general or individual permit that would impose appropriate treatment requirements prior to discharge to the stormwater drainage system.*

- *Tracking Controls:*
  - *Grade and stabilize construction site entrances and exits to prevent runoff from the site and to prevent erosion.*
  - *Install a tire washing facility at the site access to allow for tire washing when vehicles exit the site.*
  - *Remove any soil or sediment tracked off paved roads during construction by street sweeping.*
- *Non-stormwater Controls:*
  - *Place drip pans under construction vehicles and all parked equipment.*
  - *Check construction equipment for leaks regularly.*
  - *Wash construction equipment in a designated enclosed area regularly.*
  - *Contain vehicle and equipment wash water for percolation or evaporative drying away from storm drain inlets.*
  - *Refuel vehicles and equipment away from receiving waters and storm drain inlets, contain the area to prevent run-on and run-off, and promptly cleanup spills.*
  - *Cover all storm drain inlets when paving or applying seals or similar materials to prevent the discharge of these materials.*
- *Waste Management and Hazardous Materials Pollution Control:*
  - *Remove trash and construction debris from the project area daily.*
  - *Locate sanitary facilities a minimum of 300 feet from receiving waters. Maintain sanitary facilities regularly.*
  - *Store all hazardous materials in an area protected from rainfall and stormwater run-on and prevent the off-site discharge of hazardous materials.*
  - *Minimize the potential for contamination of receiving waters by maintaining spill containment and cleanup equipment on site, and by properly labeling and disposing of hazardous wastes.*
  - *Locate waste collection areas close to construction entrances and away from roadways, storm drains, and receiving waters.*
  - *Inspect dumpsters and other waste and debris containers regularly for leaks and remove and properly dispose of any hazardous materials and liquid wastes placed in these containers.*
  - *Train construction personnel in proper material delivery, handling, storage, cleanup, and disposal procedures.*
  - *Implement construction materials management BMPs for:*
    - *Road paving, surfacing and asphalt removal activities.*
    - *Handling and disposal of concrete and cement.*
- *BMP Inspection, Maintenance, and Repair:*
  - *Inspect all BMPs on a regular basis to confirm proper installation and function. Inspect BMPs daily during storms.*
  - *Immediately repair or replace BMPs that have failed. Provide sufficient devices and materials (e.g., silt fence, coir rolls, erosion blankets, etc.) throughout project construction to enable immediate corrective action for failed BMPs.*

- *Monitoring and Reporting:*
  - > *Provide the required documentation for SWPPP inspections, maintenance, and repair requirements. Personnel that will perform monitoring and inspection activities shall be identified in the SWPPP.*
  - > *Maintain written records of inspections, spills, BMP-related maintenance activities, corrective actions, and visual observations of off-site discharges of sediment or other pollutants, as required by the SFRWQCB.*
  - > *Monitor the water quality of discharges from the site to assess the effectiveness of control measures.*
- *Implement Shoreline Improvements and work over water BMPs to minimize the potential transport of sediment, debris, and construction materials to the Lower Bay during construction of shoreline improvements.*
- *Post-construction BMPs:*
  - > *Re-vegetate all temporarily disturbed areas as required after construction activities are completed. Re-vegetation shall use native, non-invasive species.*
  - > *Remove any remaining construction debris and trash from the project site and area upon project completion.*
  - > *Phase the removal of temporary BMPs as necessary to ensure stabilization of the site.*
  - > *Maintain post-construction site conditions to avoid formation of unintended drainage channels, erosion, or areas of sedimentation.*
  - > *Correct post-construction site conditions as necessary to comply with the SWPPP and any other pertinent SFRWQCB requirements.*
- *Train construction site personnel on components of the SWPPP and BMP implementation. Train personnel that will perform inspection and monitoring activities.*

Groundwater Dewatering

For construction activities that discharge to the separate storm sewer system, discharge of groundwater from temporary construction dewatering activities would be regulated by the SFRWQCB by one of several mechanisms, depending on the quality and quantity of groundwater and its potential to cause or contribute to violation of water quality standards. The permitting options are coverage under (1) the Construction General Permit; (2) one of the three General NPDES Permits regulating the discharge of extracted and treated groundwater to the storm drain system; or (3) an individual NPDES permit/WDR.[587] These permits include provisions for discharge limitations, peak flow and flow duration restrictions, other dewatering discharge requirements, and monitoring and reporting requirements.

Because permit conditions will depend upon the quality of the water discharged and the anticipated discharge rates, mitigation measure MM HY-1a.3 will require the preparation and implementation of a Groundwater Dewatering Plan to protect water quality, which shall be incorporated into the SWPPP:

[587] An NPDES permit also serves as a WDR.

MM HY-1a.3 *Groundwater Dewatering Plan. Prior to commencement of construction activities and to minimize potential impacts to receiving water quality during the construction period, the Project Applicant shall through the proper implementation of this dewatering plan, show compliance with SFRWQCB/NPDES requirements, whichever are applicable.*

The Dewatering Plan shall specify how the water would be collected, contained, treated, monitored, and/or discharged to the vicinity drainage system or Lower Bay. Subject to the review and approval of the SFRWQCB, the Dewatering Plan shall include, at a minimum:

- *Identification of methods for collecting and handling water on site for treatment prior to discharge, including locations and capacity of settling basins, infiltration basins (where not restricted by site conditions), treatment ponds, and/or holding tanks*
- *Identification of methods for treating water on site prior to discharge, such as filtration, coagulation, sedimentation settlement areas, oil skimmers, pH adjustment, and other BMPs*
- *Procedures and methods for maintaining and monitoring dewatering operations to ensure that no breach in the process occurs that could result in an exceedance of applicable water quality objectives*
- *Identification of discharge locations and inclusion of details on how the discharge would be conducted to minimize erosion and scour*
- *Identification of maximum discharge rates to prevent exceedance of storm drain system capacities*
- *Additional requirements of the applicable General Permit or NPDES Permit/WDR (including effluent and discharge limitations and reporting and monitoring requirements, as applicable) shall be incorporated into the Dewatering Plan*

Any exceedance of established narrative or numeric water quality objectives shall be reported to the SFRWQCB and corrective action taken as required by the SFRWQCB and the Dewatering Plan. Corrective action may include increased residence time in treatment features (e.g., longer holding time in settling basins) and/or incorporation of additional treatment measures (e.g., addition of sand filtration prior to discharge).

Groundwater dewatering activities could also alter the gradient of groundwater flow. However, the altered groundwater flow gradient would not be expected to cause or contribute to discharge of contaminated groundwater to the Lower Bay; groundwater would flow towards the point(s) of dewatering (internal to the site) and not towards the Lower Bay. In addition, refer to Impact HZ-5b and mitigation measure MM HZ-5a (Foundation Support Piles Installation Plan) in Section III.K for a discussion of foundation support piles installation, including the potential for groundwater contamination.

Summary (Separate Storm Sewer System)

With respect to erosion and sediment control, implementation of mitigation measures MM HY-1a.2 (SWPPP-Separate Storm Sewer System), MM HZ-1a (Article 22 Site Mitigation Plan), MM HZ-2a.1 (Unknown Contaminant Contingency Plan), MM-HZ-5a (Foundation Support Piles Installation Plan) and MM HZ-15 (Asbestos Dust Mitigation and Control Plan) would reduce the potential for contaminants, sediments, or pollutants in stormwater runoff to enter the separate sewer system. Compliance mitigation measure MM HY-1a.3 would require the preparation and implementation of a Groundwater Dewatering Plan to protect water quality. Water quality standards would not be exceeded nor would the Project cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Shoreline Activities

Development at Candlestick Point would include the repair and upgrade of existing shoreline protection features (e.g., riprap) along the majority of the shoreline (as further described and illustrated in Chapter II). Improvements to the shoreline along Candlestick Point would include the placement of additional riprap (rock) to improve the flood protection function of the existing riprap shoreline edge, the creation of a sandy recreational beach at the mid-point of the Wind Meadow reach along the Eastern Shoreline; and the creation of new tidal habitat in several locations. This would involve construction activities along the shoreline that could result in the discharge of pollutants in stormwater runoff and/or the incidental or accidental discharge of substances and materials commonly used in construction directly to the Lower Bay.

Construction activities along the shore would expose soils to rainfall, runoff, wind, and wave action, which could result in the erosion of soils, the mobilization and deposition of dust from affected areas, and the mobilization and transport of residual hazardous materials in soils to the Lower Bay. These activities could contribute construction debris and materials directly to surface waters, cause suspension of particulates, or cause re-suspension of toxic sediment-bound pollutants into the water column. The specific construction methods for in-water construction would be determined during detailed Project design, and the agencies that would provide oversight would be determined during the permit application review process.

Various permits would be likely be required to construction the Project, such as a CWA Section 404 Permit and associated CWA section 401 Water Quality Certification, a Section 10 of the *Rivers and Harbors Act* Permit, and/or a permit issued by BCDC under the *McAteer-Petris Act*. For example, in order for a Project Applicant to discharge dredged material to any water of the US, including navigable waters, Section 404 of the CWA requires an evaluation to demonstrate that there is no practicable alternative to the proposed discharge that would have less impact on the aquatic ecosystem. Most RWQCBs rely on applications for a CWA 401 Water Quality Certification (or a waiver thereof) to determine whether WDRs need to be issued for a project. Refer to Section III.N for a detailed discussion of the potential impacts to biological resources resulting from in-water construction, the permitting processes that would likely be required, and the mitigation measures that have been identified in this EIR to address biological impacts at Candlestick Point (e.g., Impact BI-4a and mitigation measures MM BI-4a.1 and MM BI-4a.2; and Impact BI-12a). Specifically, mitigation measures MM BI-4a.1 and MM BI-4a.2 provide measures to protect biological resources during construction of the shoreline improvements and also include BMPs to reduce potential effects on water quality.

It is anticipated that any permit(s) issued could include or otherwise reference the construction-related BMPs identified by the Project Applicant in the SWPPPs to reduce potential impacts to water quality (refer to mitigation measures MM HY-1a.1 and HY-1a.2). Further, additional BMPs may be specified by the agencies to further protect water quality along the shoreline. For example, typical BCDC permit conditions include requirements to construct, guarantee, and maintain public access to the Bay, specified construction methods to ensure safety or to protect water quality, plan review requirements that must be met before construction can begin, and mitigation requirements to offset adverse environmental impacts.

With respect to water quality impacts caused by the shoreline improvements at Candlestick Point, including pollutants transported through erosion and sedimentation, the incidental release of construction materials, or the accidental spill of substances commonly used in construction directly to the Lower Bay, implementation of mitigation measures MM HY-1a.1 (SWPPP and ESCP – Combined Sewer System),

MM HY-1a.2 (SWPPP – Separate Storm Sewer System), MM HZ-1a (Article 22 Site Mitigation Plan), and MM HZ-2a.1 (Unknown Contaminant Contingency Plan) would reduce the potential for contaminants, sediments, or pollutants in stormwater runoff to enter the Lower Bay. While mitigation measures MM HY-1a.1 and MM HY-1a.2, each of which require the preparation of a SWPPP, are intended to address runoff that enters either the combined or separate sewer systems, the BMPs could also address shoreline improvement activities.

Summary of Impact at Candlestick Point

These mitigation measures, which shall be implemented by the Project Applicant, would ensure that water quality standards would not be exceeded nor would the Project cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Impact of Hunters Point Shipyard Phase II

Impact HY-1b **Construction at HPS Phase II would not cause an exceedance of water quality standards or contribute to or cause a violation of waste discharge requirements. (Less than Significant with Mitigation) *[Criterion M.a]***

The discharge of sediment-laden runoff, groundwater from temporary construction dewatering activities, the incidental or accidental release of construction materials or products into the combined sewer system, separate storm sewer systems, or directly to receiving waters within or adjacent to the Project site, or the exposure of surface water or groundwater to contaminated soils could impair water quality.

Construction activities within HPS Phase II would include demolition of existing facilities, the clearing and grading of development areas (including excavation, trenching, movement of soil, and the importation of fill soils), and the subsequent construction of new facilities and associated infrastructure. Construction activities would expose soils to rainfall and runoff, construction vehicle traffic, and wind, which could result in the erosion of soils and the mobilization and deposition of dust from disturbed development areas.

Construction activities could also result in the incidental release of construction materials or the accidental spill of substances commonly used in construction (e.g., paints, solvents, petroleum products, equipment leakage, and others). The incidental release or accidental spill of such substances could result in the introduction of those substances directly to the Lower Bay or into stormwater runoff, and their subsequent discharge to the separate sewer system.

Construction activities could also disturb contaminated soils and increase their exposure to surface water runoff and cause or contribute to surface water or groundwater quality degradation. The historic uses at HPS Phase II by both the Navy and its tenants resulted in a number of hazardous materials release sites that are presently undergoing remediation by the Navy under federal law and under the supervision of federal and state environmental agencies. The potential for such contamination to be encountered during construction is addressed in Section III.K.

Construction of the Project would require excavation of portions of the site for building foundations, basements, utilities, or mechanical equipment that may be installed below grade. Excavation and grading could encounter groundwater. The installation of below-grade building elements could, therefore, require temporary dewatering and the short-term discharge of groundwater to the separate storm sewer system.

Separate Storm Sewer System

Erosion and Sediment Control

As discussed in Impact HY-1a, in areas that drain to a separate storm sewer system, construction runoff would not be treated in the combined sewer system, which could result in the potential for pollutants in stormwater runoff to discharge to the Bay. In these areas, or in areas that discharge runoff directly to the Bay (such as sheet flow from the CPSRA), the Project Applicant would be required to comply with the state's Construction General Permit, including development, implementation, and submittal of a SWPPP (which is required by mitigation measure MM HY-1a.2 (SWPPP-Separate Storm Sewer System) that includes minimum BMP requirements, depending upon the Risk Level Determination. The discussion provided in Impact HY-1a regarding the regulatory systems in place that address the potential for pollutants to be transported in stormwater to the separate storm sewer system (thereby affecting water quality) would also apply to HPS Phase II.

The historic uses at HPS Phase II by both the Navy and its tenants resulted in a number of hazardous materials release sites that are presently undergoing remediation by the Navy under federal law and under the supervision of federal and state environmental agencies. Prior to the transfer of HPS Phase II property to the City, the Navy must ensure, to the satisfaction of the Federal Facilities Agreement (FFA) signatories, that the Project site is suitable for conveyance for the use intended and that the intended use is consistent with the protection of human health and the environment (refer also to Section III.K for further detail). As discussed in Section III.K, the Navy would be required to implement Institutional Controls (ICs) for cleanup at HPS Phase II. ICs are legal and administrative mechanisms to implement land use restrictions to limit the exposure of future landowners and users to hazardous materials and to ensure the integrity of remedial activities. ICs are required when a property is remediated to cleanup levels that do not allow for unlimited use and unrestricted exposure. As noted in Section III.K., the HPS Phase II site is contaminated by past use and would likely continue to retain residual hazardous material contamination after transfer of the site from the Navy to San Francisco Redevelopment Agency and the Project Applicant.

During construction, stormwater runoff over disturbed, contaminated soils could transport contaminated sediment to surface water or mobilize residual pollutants and transport them to surface waters. Additionally, infiltration of rainfall through disturbed areas, including disturbance of interim or permanent caps and covers, could alter the local groundwater gradient and cause or contribute to migration of groundwater pollutants to the Lower Bay. However, when determined necessary by Article 22A of the Health Code, mitigation measures MM HZ-1a (Article 22 Site Mitigation Plan) would require a Site Mitigation Plan and MM HZ-2a.1 (Unknown Contaminant Contingency Plan) would require a contingency plan to address the discovery of unknown contaminated areas. Implementation of mitigation measure MM HY-1a.2 (SWPPP-Separate Storm Sewer System) would require the identification of BMPs to protect water quality during construction activities. Implementation of mitigation measure MM HZ-12 (Compliance with Administrative Order of Consent at Early Transferred Parcels) would require compliance by the Agency or Project Applicant with all requirements incorporated into remedial design documents, dust control plans, and any other document required under the Administrative Order of Consent. Implementation of mitigation measure MM HZ-15 (Asbestos Dust Mitigation and Control Plans) would require implementation of appropriate plans control dust that may contain naturally-occurring asbestos.

Water quality standards would not be exceeded nor would the development at HPS Phase II cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Groundwater Dewatering

For construction activities that discharge to the separate storm sewer system, discharge of groundwater from temporary construction dewatering activities would be regulated by the SFRWQCB by one of several mechanisms, depending on the quality and quantity of groundwater and its potential to cause or contribute to violation of water quality standards. The permitting options are coverage under (1) the Construction General Permit; (2) one of the three General NPDES Permits regulating the discharge of extracted and treated groundwater to the storm drain system; or (3) an individual NPDES permit/WDR.[588] These permits include provisions for discharge limitations, peak flow and flow duration restrictions, other dewatering discharge requirements, and monitoring and reporting requirements.

Because permit conditions will depend upon the quality of the water discharged and the anticipated discharge rates, mitigation measure MM HY-1a.3 will require the preparation and implementation of a Groundwater Dewatering Plan to protect water quality. Compliance mitigation measure MM HY-1a.3 would protect water quality. Water quality standards would not be exceeded nor would the Project cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Shoreline Activities

Development at HPS Phase II would include the repair and upgrade of existing shoreline protection features (e.g., riprap) and the construction of new shoreline protection features along the majority of the shoreline (as further described and illustrated in Chapter II). Along some areas of the HPS Phase II shoreline, piers and wharves have deteriorated due to structure age and lack of maintenance, and near-shore settlement has occurred. Repairs of existing HPS Phase II shoreline structures vary based on type of edge and include repair of piles and deck, concrete crack repairs and rock buttresses along base of the drydocks, removal of upper portion of fill along bulkheads, and rip-rap placement. Several piers and drydocks would be modified by the removal of short section of piers and/or bulkheads (near the shore) to preclude public access, thereby creating opportunities for waterbirds to roost on the retained portions of these structures.

The Shipyard currently includes seven piers and six drydocks along the shoreline (refer to Figure II-2). As part of the base closure and conveyance process described in Chapter I (Introduction), the Navy will remove Piers B and C and timber portions (concrete walls would remain) of Drydocks 5, 6, and 7 prior to conveyance of HPS Phase II to the City and County of San Francisco. Drydocks 2 and 3 and four supporting buildings (Buildings 140, 204, 205, and 207) were previously identified as historic resources eligible for listing in the National Register of Historic Places.[589] Heritage Park is proposed at Drydocks 2 and 3 and would display interpretive elements related to the history of HPS. Drydocks 4, 5, 6 and 7 and the Re-Gunning Pier and crane would remain. Piers 1, 2, and 3 consist of long, narrow concrete piers in

[588] An NPDES permit also serves as a WDR.
[589] City and County of San Francisco and San Francisco Redevelopment Agency, Final Environmental Impact Report for the Reuse of Hunters Point Shipyard, February 8, 2000. This document is on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

the southeastern portion of HPS Phase II. These pier structures would remain in place, but portions of the pier would be removed to prevent public access for safety reasons. The Re-gunning Pier would be reconfigured for wildlife habitat uses. Some pier areas would require cleaning and repaving. The North and South Piers would be the sites of the proposed marina.

Construction at HPS Phase II would also involve the installation of a marina and the installation of breakwaters to protect the marina. The 300-slip marina will require the construction of two breakwater sections ranging between 300 and 650 feet in length. To accommodate the proposed marina, breakwaters will be constructed using two 10.7 to 11.3 acres basins. They will be constructed off site using concrete sheet pile supported by batter piles and installed using water-based equipment.

These improvements would involve construction activities along the shoreline that could result in the discharge of pollutants in stormwater runoff and/or the incidental or accidental discharge of substances and materials commonly used in construction directly to the Lower Bay.

The demolition of existing piers or parts of piers could generate dust and debris and mobilize underwater sediments in vicinity of the removed pilings. The construction of new in-water pilings, shoreline abutments, and the breakwater could also mobilize underwater sediments, re-suspend sediment-associated contaminants in the water column, as well as potentially result in the incidental release of construction materials (i.e., sawdust, metal fragments, concrete) or the accidental spill of construction materials (i.e., paints and solvents) or substances commonly used in construction equipment (i.e., petroleum products).

The discussion provided in Impact HY-1a regarding the regulatory systems in place that address in-water construction (thereby affecting water quality) would also apply to HPS Phase II. In addition, refer to Impact HZ-5a and mitigation measure MM HZ-5a in Section III.K for a discussion of installation of foundation support piles, including the potential for groundwater contamination. Refer to Impact HZ-10 and mitigation measures MM HZ-10b (Regulatory Agency Approved Workplans and Permits for Shoreline Improvements), for a discussion of methods to reduce the potential of encountering contaminated sediments while implementing shoreline improvements.

The shoreline improvements at HPS Phase II are more extensive than those proposed for Candlestick Point. With respect to water quality impacts caused by the shoreline improvements at HPS Phase II, including pollutants transported through erosion and sedimentation or the incidental release of construction materials or the accidental spill of substances commonly used in construction directly to the Lower Bay, implementation of mitigation measures MM HY-1a.1 (SWPPP—Combined Sewer System), MM HY-1a.2 (SWPPP—Separate Storm Sewer System), MM HZ-1a (Article 22 Site Mitigation Plan), and MM HZ-2a.1 (Unknown Contaminant Contingency Plan) would reduce the potential for contaminants, sediments, or pollutants in stormwater runoff to enter the Lower Bay. While mitigation measures MM HY-1a.1 and MM HY-1a.2, each of which require the preparation of a SWPPP, are intended to address runoff that enters either the combined or separate sewer systems, the BMPs could also address shoreline improvement activities.

Refer to Section III.N for a detailed discussion of the potential impacts to biological resources resulting from in-water construction, the permitting processes that would likely be required, and the mitigation measures that have been identified in this EIR to address biological impacts at HPS Phase II (e.g., Impact BI-4a and mitigation measures MM BI-4a.1 (Wetlands and Jurisdictional/Regulated Waters

Mitigation for Temporary and/or Permanent Impacts) and MM BI-4a.2 (Wetlands and Jurisdictional/Regulated Waters Impact Minimization for Construction-Related Impacts); Impact BI-5b and mitigation measure MM BI-5b.4 (Eelgrass Water Quality BMPs); and Impact BI-12b and mitigation measures MM BI-12b.1 (Essential Fish Habitat Avoidance and Minimization Measures) and MM BI-12b.2 (Deconstruction/Construction Debris Recovery). Each of these mitigation measures provides specific mechanisms to protect biological resources and reduce potential effects on water quality during construction of the shoreline improvements.

Summary of Impact at Hunters Point Shipyard, Phase II

All of the mitigation measures referenced in this discussion would ensure that water quality standards would not be exceeded nor would construction and HPS Phase II cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Impact of Yosemite Slough Bridge

Impact HY-1c **Construction of the Yosemite Slough bridge would not cause an exceedance of water quality standards or contribute to or cause a violation of waste discharge requirements. (Less than Significant with Mitigation) *[Criterion M.a]***

The Yosemite Slough bridge would involve the installation of pilings in the slough, bridge foundations along either edge of the slough, and the installation of the bridge deck surface, which is proposed to include both paved and turf-covered areas. Installation of the bridge pilings could require the installation of sheet piles on either side of the bridge location to form a barrier on either side of the construction site from which water would be removed, followed by the subsequent installation of the bridge pilings and the bridge deck. The installation of sheet piles that form coffer dams on either side of the bridge, bridge pilings, and the bridge foundations could mobilize underwater sediments and re-suspend sediment-associated contaminants into the water column, and result in the incidental release of construction materials (e.g., sawdust, metal fragments, concrete), or the accidental spill of construction materials (e.g., paints and solvents) or substances commonly used in construction equipment (e.g., petroleum products).

With respect to water quality impacts caused by construction of the Yosemite Slough bridge, including pollutants transported through erosion and sedimentation or the incidental release of construction materials or the accidental spill of substances commonly used in construction directly to the Lower Bay, implementation of mitigation measures MM HY-1a.1 (SWPPP—Combined Sewer System), MM HY-1a.2 (SWPPP—Separate Storm Sewer System), MM HZ-1a (Article 22 Site Mitigation Plan), MM HZ-2a.1 (Unknown Contaminant Contingency Plan), and MM HZ-9 (Navy-Approved Workplans for Construction and Remediation Activities on Navy-Owned Property) would reduce the potential for contaminants, sediments, or pollutants in stormwater runoff to enter the Lower Bay. While mitigation measures MM HY-1a.1 and MM HY-1a.2, each of which require the preparation of a SWPPP, are intended to address runoff that enters either the combined or separate sewer systems, the BMPs could also address bridge construction activities. In addition, because the bridge would be constructed using piles driven in dry conditions (behind coffer dams), water quality impacts would be minimized.

Refer to Section III.N for a detailed discussion of the potential impacts to biological resources resulting from in-water construction, the permitting processes that would likely be required, and the mitigation measures that have been identified in this EIR to address biological impacts associated with construction of the Yosemite Slough bridge. Implementation of mitigation measures MM BI-4a.1 (Wetlands and Jurisdictional/Regulated Waters Mitigation for Temporary and/or Permanent Impacts), MM BI-4a.2 (Wetlands and Jurisdictional/Regulated Waters Impact Minimization for Construction-Related Impacts); MM BI-12b.1 (Essential Fish Habitat Avoidance and Minimization Measures) and MM BI-12b.2 (Deconstruction/Construction Debris Recovery) would provide specific mechanisms to protect biological resources and reduce potential effects on water quality during construction of Yosemite Slough bridge.

Summary of Impact at Hunters Point Shipyard, Phase II

All of the mitigation measures referenced in this discussion would ensure that water quality standards would not be exceeded nor would the Project cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Combined Impact of Candlestick Point, Hunters Point Shipyard Phase II, and Yosemite Slough Bridge

Impact HY-1 **Construction activities associated with the Project would not cause an exceedance of water quality standards or contribute to or cause a violation of waste discharge requirements. (Less than Significant with Mitigation)** ***[Criterion M.a]***

As previously discussed, the discharge of sediment-laden runoff, groundwater from temporary construction dewatering activities, the incidental or accidental release of construction materials or products into the combined sewer system, separate storm sewer systems, or directly to receiving waters within or adjacent to the Project site, or the exposure of surface water or groundwater to contaminated soils could impair water quality.

Construction of the Project would include demolition of existing facilities, the clearing and grading of development areas (including excavation, trenching, movement of soil, and the importation of fill soils), and the subsequent construction of new facilities and associated infrastructure, including the Yosemite Slough bridge, the various shoreline improvements, and the marina and breakwaters. Construction activities would expose soils to rainfall and runoff, construction vehicle traffic, and wind, which could result in the erosion of soils and the mobilization and deposition of sediment from disturbed development areas, including those that may contain contamination. Construction activities could also result in the incidental release of construction materials or the accidental spill of substances commonly used in construction (e.g., paints, solvents, petroleum products, equipment leakage, and others). The incidental release or accidental spill of such substances could result in the introduction of those substances directly to the Lower Bay or into stormwater runoff that could discharge into the combined or separate sewer system.

Construction of the Project would require excavation of portions of the site for building foundations, basements, utilities, or mechanical equipment that may be installed below grade. Excavation and grading could encounter groundwater. The installation of below-grade building elements could, therefore, require temporary dewatering and the short-term discharge of groundwater to either the combined sewer system or separate storm sewer systems.

Erosion and Sediment Control

As previously discussed, portions of Candlestick Point drain to the combined sewer system, while other portions discharge directly to the Lower Bay (via sheet flow) or drain to separate storm sewer systems that then drain to the Lower Bay. HPS Phase II drains to the separate storm sewer system. The combined sewer system collects and treats stormwater flows prior to discharge to the Lower Bay; however, there is currently no treatment of stormwater runoff that drains to the Lower Bay via direct discharges or separate sewer systems.

Construction-related discharges to the combined system would need to comply with Article 4.1 of the *San Francisco Public Works Code* and meet the requirements of the City's Construction Site Runoff Pollution Prevention Program. The City's Construction Site Runoff Pollution Prevention procedures were established to ensure that all businesses comply with all appropriate stormwater laws and other City requirements, and includes inspection of construction sites to ensure compliance. Under this program, all construction sites must prepare a SWPPP, which includes an ESCP, as further required by mitigation measure MM HY-1a.1.

In areas served by a separate storm sewer system, or in areas that discharge runoff directly to the Bay (such as sheet flow from the CPSRA), the Project Applicant would be required to comply with the state's Construction General Permit, including development, implementation, and submittal of a SWPPP (which is required by mitigation measure MM HY-1a.2) that includes minimum BMP requirements, depending upon the Risk Level determination according to the Construction General Permit.

Groundwater Dewatering

For construction activities that discharge to the combined system, discharge of groundwater from temporary construction dewatering activities would be regulated under Article 4.1 of the *San Francisco Public Works Code*, which prohibits the discharge of hazardous waste and other pollutants that violate the City's federal and state NPDES permits. These NPDES Permits establish the waste discharge requirements for the combined sewer system.

Pursuant to Article 4.1 of the *San Francisco Public Works Code*, discharges of dewatering water to the combined sewer system would be regulated under a Batch Wastewater Discharge permit that would be obtained by the Applicant from the SFPUC. Specific permit terms and conditions are imposed by SFPUC to maintain SFPUC's compliance with its own Wastewater Discharge Permit issued by the SFRWQCB. Under the Batch Wastewater Discharge permit, the discharge must meet specific numeric effluent limitations for toxic and conventional pollutants and monitoring is required to ensure compliance. [590]

For construction activities that discharge to the separate storm sewer system, discharge of groundwater from temporary construction dewatering activities would be regulated by the SFRWQCB by one of several mechanisms, depending on the quality and quantity of groundwater and its potential to cause or contribute to violation of water quality standards. The permitting options are coverage under (1) the Construction General Permit (for uncontaminated groundwater); (2) one of the three General NPDES Permits regulating the discharge of extracted and treated groundwater to the storm drain system; or (3) an individual NPDES

[590] San Francisco Public Utilities Commission, 2008, Requirements for Batch Wastewater Discharges and associated Appendixes, July 10, 2008.

permit/WDR.[591] These permits include provisions for discharge limitations, peak flow and flow duration restrictions, other dewatering discharge requirements, and monitoring and reporting requirements.

Because permit conditions will depend upon the quality of the water discharged and the anticipated discharge rates, mitigation measure MM HY-1a.3 will require the preparation and implementation of a Groundwater Dewatering Plan to protect water quality; the Groundwater Dewatering Plan shall be incorporated into the SWPPP. Compliance with mitigation measure MM HY-1a.3 would protect water quality. Water quality standards would not be exceeded nor would the Project cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Shoreline Activities

As further discussed in Impact HY-1a, Impact HY-1b, and Impact HY-1c, development of the Project would include the repair and upgrade of existing shoreline protection features (e.g., riprap) and the construction of new shoreline protection features along the majority of the shoreline (as further described and illustrated in Chapter II).

Summary

With respect to erosion and sediment control, implementation of mitigation measures MM HY-1a.1 (SWPPP - Combined Sewer System), MM HY-1a.2 (SWPPP-Separate Storm Sewer System), MM HZ-1a (Article 22 Site Mitigation Plan), MM HZ-2a.1 (Unknown Contaminant Contingency Plan), MM HZ-9 (Navy-Approved Workplans for Construction and Remediation Activities on Navy-Owned Property), MM HZ-12 (Compliance with Administrative Order of Consent at Early Transferred Parcels), and MM HZ-15 (Asbestos Dust Mitigation and Control Plans)would reduce the potential for contaminants, sediments, or pollutants in stormwater runoff to enter the combined or separate sewer system. Compliance with Article 4.1, including regulation under SFPUC's Batch Wastewater Discharge permit, would reduce the potential for pollutant discharges caused by groundwater dewatering to enter the combined sewer system. Implementation of mitigation measure MM HY-1a.3 would reduce the impacts of discharging dewatered groundwater into the separate sewer system. Water quality standards would not be exceeded nor would the Project cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

With respect to water quality impacts caused by the shoreline improvements at Candlestick Point, including pollutants transported through erosion and sedimentation or the incidental release of construction materials or the accidental spill of substances commonly used in construction directly to the Lower Bay, implementation of mitigation measures MM HY-1a.2 (SWPPP and ESCP—Combined Sewer System), MM HY-1a.2 (SWPPP—Separate Storm Sewer System), MM HZ-1a (Article 22 Site Mitigation Plan), MM HZ-2a.1 (Unknown Contaminant Contingency Plan), and MM HZ-10b (Regulatory Agency-Approved Workplans and Permits for Shoreline Improvements) would reduce the potential for contaminants, sediments, or pollutants in stormwater runoff to enter the Lower Bay. While mitigation measures MM HY-1a.1 and MM HY-1a.2, each of which require the preparation of a SWPPP, are intended to address runoff that enters either the combined or separate sewer systems, the BMPs could also address shoreline improvement activities.

[591] An NPDES permit also serves as a WDR.

Refer to Section III.N for a detailed discussion of the potential impacts to biological resources resulting from in-water construction, the permitting processes that would likely be required, and the mitigation measures that have been identified in this EIR to address biological impacts at HPS Phase II, including MM BI-4a.1 (Wetlands and Jurisdictional/Regulated Waters Mitigation for Temporary and/or Permanent Impacts), MM BI-4a.2 (Wetlands and Jurisdictional/Regulated Waters Impact Minimization for Construction-Related Impacts), MM BI-5b.4 (Eelgrass Water Quality BMPs), MM BI-12b.1 (Essential Fish Habitat Avoidance and Minimization Measures) and MM BI-12b.2 (Deconstruction/Construction Debris Recovery). Each of these mitigation measures provides specific mechanisms to protect biological resources and reduce potential effects on water quality during in-water construction activities.

All of the mitigation measures referenced in this discussion would ensure that water quality standards would not be exceeded nor would the Project cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Impact HY-2: Groundwater Supplies and Groundwater Recharge

Impact HY-2 **Construction activities associated with the Project would not substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level. (Less than Significant)** ***[Criterion M.b]***

Groundwater would not be used for any construction activities such as dust control or irrigation of vegetated erosion control features; no groundwater wells would be developed as part of the Project and no on-site groundwater wells would be used for water supplies. Short-term construction groundwater dewatering may be necessary at certain locations (e.g., for installation of building foundations or underground utilities), but dewatering would have only a minor temporary effect on the groundwater table elevation in the immediate vicinity of the activity, and would not measurably affect groundwater supplies. Further, the shallow groundwater underlying the Project site at Candlestick point or HPS Phase II is not used for water supply. Construction activities would generally occur within areas that are already developed, and much of the existing open space would remain undeveloped and continue to contribute to groundwater recharge. Construction of the Project would include installation and operation of groundwater remediation and monitoring wells, if required by Navy transfer documents and regulatory requirements (as discussed in Section III.K). Therefore construction at the Project would not substantially deplete groundwater supplies or interfere substantially with groundwater recharge, and this impact would be less than significant. No mitigation is required.

Impact HY-3: Erosion and Siltation Effects

Impact HY-3 **Construction activities associated with the Project would not substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on or off site. (Less than Significant) *[Criterion M.c]***

Construction activities associated with the Project would include site clearance, grading and excavation, and the construction of new buildings and infrastructure. The potential for on-site erosion of exposed soil surfaces during construction activity is fully addressed in Impact HY-1. No streams or rivers exist in the immediate vicinity of the Project site, and thus, no streams or rivers would be altered by construction activity. As discussed in the setting, stormwater at the Project site either drains to storm drains (which include both combined and separate systems), or drains directly to the Bay via surface runoff (generally only along the shoreline). The existing drainage patterns would be generally preserved, although as noted in Chapter II, the ground elevation would be raised (via the importation of fill soils) to protect the area from a potential rise in sea level of up to three feet. This would locally modify drainage patterns within the affected area. Because most of the affected area is already drained by sewer systems (combined and separate), and would continue to drain to a newly constructed entirely separate storm sewer systems, this would not result in a substantial alteration of drainage patterns related to erosion potential. Potential effects of cut and fill activities on slope stability and erosion are addressed in Section III.L. Therefore, construction at the Project site would not substantially alter the existing drainage pattern of the site or area such that on- or off-site erosion is substantially increased and this impact would be less than significant. No mitigation is required.

Impact HY-4: Flooding Effects

Impact HY-4 **Construction activities associated with the Project would not substantially alter the existing drainage pattern of the site, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on or off site. (Less than Significant with Mitigation) *[Criterion M.d]***

No streams or rivers exist within the Project site, and thus, no streams or rivers would be altered by construction activity. The amount of impervious area would not increase; impervious areas would be removed and/or replaced and the Project site would be graded flat (0.1 to 0.5 percent grade), resulting in no increase in stormwater runoff during construction. As discussed under Impact HY-3, construction activities at the Project site would not substantially alter existing drainage patterns causing or contributing to increased stormwater runoff. Construction would include clearance, grading, and excavation, and the subsequent construction of new buildings and infrastructure. With implementation of mitigation measures MM HY-1a.1 and MM HY-1a.2 (preparation of a SWPPP with BMPs to collect, retain as appropriate, and discharge stormwater runoff), and MM HY-1a.3 (Construction Dewatering Plan), construction of the Project would not substantially alter the existing drainage pattern of the site or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site, and this impact would remain at a less-than-significant level.

Impact HY-5: Storm Sewer System Capacity

Impact HY-5 **Construction activities associated with the Project would not create or contribute runoff water that would exceed the capacity of existing or planned storm sewer systems or provide substantial additional sources of polluted runoff. (Less than Significant with Mitigation) *[Criterion M.e]***

Management of runoff within portions of the Project site affected by construction activity discharging directly to the Bay or to a separate storm drain system would be governed by the conditions of a SWPPP developed per Construction General Permit requirements, as required by mitigation measure MM HY-1a.2, which would include measures to collect, retain, and discharge runoff in ways that do not overwhelm the capacity of existing downstream drainage facilities. Management of runoff from areas draining to the combined sewer system would be governed by conditions of a SWPPP with an ESCP, developed per SFPUC requirements.

As described in Impact HY-1, dewatering to the combined sewer system would require a Batch Wastewater Discharge Permit from the SFPUC. Permit conditions are specified by the SFPUC to prevent violation of the SFPUC's Wastewater Discharge Permit, including conveyance capacity constraints and effluent limits. Dewatering discharges to the separate sewer system would be governed by conditions of the Construction General Permits, other general permits, or an individual NPDES Permit/WDR, as specified by the SFRWQCB.

As discussed in Impacts HY-3 and HY-4, construction of the Project would not be expected to greatly alter Project site drainage such that stormwater runoff is increased. During construction, existing stormwater drainage facilities would be replaced by new, entirely separate sewer systems that would collect and treat Project site stormwater flows. This new storm drain system would be designed and sized in accordance with the City of San Francisco Subdivision Regulations and would also be sized to accommodate 5-year storm event flows from upstream contributing areas (HPS Phase I). In accordance with City design criteria, the newly piped storm drain system would be sized to convey the 5-year storm event when flowing full or surcharged (overloaded/flooded) and runoff from the 5-year storm event up to the 100-year storm event would be contained within the streets and drainage channels rights-of-way.

Impacts associated with additional sources of polluted runoff are addressed in Impact HY-1. As discussed under Impact HY-1, implementation of mitigation measures would reduce potential for construction activities to generate additional sources of polluted runoff to a less-than-significant level.

Operational Impacts

Impact HY-6: Water Quality Standards and Waste Discharge Requirements

Impact of Candlestick Point

This discussion addresses whether the Project could result in a violation of either water quality standards or waste discharge requirements. As previously mentioned, the CWA requires each state to adopt water quality standards which consist of designated beneficial uses and with water quality objectives. Discharges from the combined sewer system are regulated under two NPDES that identify specific WDRs. Stormwater runoff discharges from municipal separate stormwater systems (or MS4s) are regulated under the statewide

Phase II NPDES General Permit for Storm Water Discharges from Small MS4s (Municipal Stormwater General Permit)(Order No. 2003-0005-DWQ), which requires the development of a Stormwater Management Plan (SWMP) with the goal of reducing the discharge of pollutants to the maximum extent possible (MEP). If recycled water was used for irrigation of landscaping, such use would be subject to the General Waste Discharge Requirements for Landscaping Irrigation Uses of Municipal Recycled Water (Recycled Water General Permit)(Order No. 2009-0006-DWQ). In addition, the State's Antidegradation Policy requires that actions which can adversely affect water quality must: (1) be consistent with maximum benefit to the people of the State; (2) not unreasonably affect present and anticipated beneficial use of the water; and (3) not result in water quality less than that prescribed in water quality plans and policies, (i.e., will not result in exceedances of water quality objectives).

Impact HY-6a Implementation of the Project at Candlestick Point would not contribute to violations of water quality standards or waste discharge requirements. (Less than Significant with Mitigation) *[Criterion M.a]*

Stormwater Runoff

With development of Candlestick Point, stormwater runoff would be treated and conveyed through separate stormwater drainage systems. As such, the applicable WDR would be the Municipal Stormwater General Permit. Development of portions of Candlestick Point would result in the creation or replacement of impervious surfaces that would contribute to stormwater runoff and mobilize pollutants generated by the proposed land uses at Candlestick Point. The Project would remove existing structures, including Alice Griffith Housing, Candlestick Park stadium, and the parking lots surrounding the stadium; approximately 178.5 acres[592] of impervious surfaces. Development at Candlestick Point would include residential, commercial, office, and recreational uses, which could result in approximately 165.4 acres[593] of impervious surfaces. Development at Candlestick Point would, therefore, result in a 7.3 percent reduction in impervious surfaces. This reduction in impervious surface would reduce the volume of stormwater runoff from this area and reduce the surface area where pollutants could be deposited and subsequently transported in stormwater runoff.

Development at Candlestick Point would result in a change in land uses, from residential, a stadium and parking lots, to mixed land uses, including residential, commercial, office, and recreational uses. This change in land uses would affect the types and amounts of pollutants that could be present in stormwater runoff. As discussed above in the Analytic Method, typical stormwater pollutants from mixed land uses may include sediment, nutrients, heavy metals, pathogens, petroleum hydrocarbons, pesticides and other organic compounds, oxygen demanding substances, and trash and debris (refer to Table III.M-2). Stormwater runoff may be a potential source of mercury and PCBs, which are COCs because of the established and pending TMDLs for those substances. Redevelopment of Candlestick Point would remove most of the existing structures and infrastructure which could be historic sources of PCBs, thus reducing any potential discharges. However, the Project operation could be a source of mercury, which could originate from fluorescent light bulbs, mercury-containing instruments, and other sources. As discussed under Impact HY-1a, no known soil contamination is present at Candlestick Point and implementation of

[592] IBI Group, August 21, 2009.
[593] IBI Group, August 21, 2009.

mitigation measures MM HZ-1a (Article 22 Site Mitigation Plan), and MM HZ-2a.1 (Unknown Contaminant Contingency Plan) would ensure remediation of contaminated soils during construction.

Effects of development on water quality were estimated by calculating existing and potential future mean annual pollutant loads. Mean annual pollutant loads are a function of the concentration of pollutants, which is affected by land use, and the volume of runoff from an area, which is affected by the extent of impervious surfaces.

Stormwater pollutant mean annual loads were estimated using the Simple Method, developed based on empirical relationships observed in data collected in the Washington, D.C. area for the Nationwide Urban Runoff Program (NURP) studies published by USEPA in 1983.[594] As no monitoring data is available for runoff from Candlestick Point, pollutant concentrations[595] used in this analysis were derived from a combination of Los Angeles County Department of Public Works (LACDPW) monitoring data and Bay Area Stormwater Management Agencies Association (BASMAA) data; the best available data for the Project area and the proposed land uses. For each parameter, the same data set (either LACDPW or BASMAA) was used for all land use categories for that parameter. Therefore, although the estimated pollutant loads may not be reflective of actual site conditions (as no monitoring data is available), the relative differences resulting from changes in land use should conservatively reflect the change in stormwater quality associated with the proposed development. Refer to Appendix M1 for further description of the methodology and calculations.

The results of this analysis are provided in Table III.M-3 (Estimated Change in Annual Pollutant Loads from Candlestick Point Without BMPs[596]), which quantifies the change in annual pollutant loads[597] compared to existing conditions. Table III.M-3 also shows the change in the mean annual stormwater runoff volume associated with the Project (in acre-feet). To provide a conservative analysis, stormwater BMPs were not included in the analysis because specific details of the stormwater treatment BMPs that would be implemented with development have yet to be identified.

As shown in Table III.M-3, except for ammonia and total kjeldahl nitrogen (which show no change in loadings), development of Candlestick Point would result in a reduction in annual stormwater pollutant loads of between 8 and 67 percent, although these estimated loads do not account for the effect of any treatment measures, for either the existing condition (as some flows are currently discharged the combined system and treated at the SWPCP) or future conditions (as all flows up to the design storm would be treated via on-site BMPs). Table III.M-3 also shows that development of Candlestick Point would reduce stormwater runoff volumes by 37 percent, not accounting for volume reductions by BMPs.

---

[594] Center for Watershed Protection. No Date. The Simple Method to Calculate Urban Stormwater Loads. http://www.stormwatercenter.net/monitoring%20and%20assessment/simple%20meth/simple.htm (accessed September 26, 2009).

[595] The concentration of a pollutant is measured in terms of mass per volume (e.g., mg/L).

[596] The data presented in Table III.M-3 is based on estimated site runoff, land use categories, and existing literature values, as described in Appendix M1, Stormwater Runoff Calculations. While literature values cannot be used to identify specific effects or concentrations, they are reasonable for identifying relative changes resulting from changes in land use and runoff.

[597] Pollutant loads are the amount of pollutants entering a water body, generally expressed in terms of mass released over a given time frame (e.g., pounds/day).

Table III.M-3 Estimated Change in Annual Pollutant Loads from Candlestick Point Without BMPs

	Existing			*Project*		
					Difference (Existing – Project)[a]	
Pollutant	*Combined (lbs)*	*Separate (lbs)*	*Total (lbs)*	*Total (lbs)*	*(lbs)*	*(%)*

SOURCE: PBS&J 2009

a. The 'Difference' columns denote the difference between Project and Existing annual pollutant loads; a negative difference indicates that pollutant loads are lower with development of the Project compared to existing conditions.

The estimated increase in ammonia would result from the conversion of Candlestick Park stadium and associated parking lots to a mix of residential, commercial and open space. The concentration of ammonia (in the cited literature) from residential and open space land uses is approximately four times the concentration from commercial lands (which was conservatively used to estimate existing loads from the stadium and parking lots). Thus, although development at Candlestick Point would mostly decrease pollutant concentrations, it could increase the concentrations of ammonia in stormwater runoff.

Development at Candlestick Point would be required to comply with the provisions of Municipal Stormwater General Permit and the associated SWMP, the Draft San Francisco Stormwater Design Guidelines, and San Francisco Green Building Ordinance. Consistent with these requirements, the Project Applicant would be required to submit a Stormwater Drainage Master Plan (SDMP) and Stormwater Control Plan (SCP) to the SFPUC, to identify the specific stormwater treatment BMPs that would be implemented.

When finalized, the Stormwater Design Guidelines[598] are anticipated to apply to all projects greater than 5,000 square feet, and projects in areas subject to San Francisco's Green Building Ordinance, including Candlestick Point. Per the guidelines, the performance standard requires the capture and treatment of

[598] Draft Stormwater Design Guidelines were released in February 2009[598] and are expected to be adopted by the end of 2009.

runoff from either: 0.75 inch of precipitation (if volume-based BMPs are used) or a rainfall intensity of 0.2 inch per hour (if flow-based BMPs are used).

Preliminary stormwater infrastructure plans for Candlestick include a dual-pipe system to convey stormwater runoff; one system would treat runoff at the parcel level, and a second system would convey runoff from roads to centralized facilities for treatment. The Project Applicant has also developed a stormwater LID Study,[599] which summarizes preliminary concepts for the integration of these two systems by distributing BMPs throughout the site, so that runoff is treated close to the source. Some of the types of BMPs that may be implemented at the Candlestick Point include:

- Dry Detention Ponds/Dry Ponds
- Infiltration Basins
- Wetland Basins
- Biofilter
- Vegetated Swales and Filter Strips
- Grassed Channels
- Bioretention
- Media Filters
- Hydrodynamic Separators
- Pervious Pavement

The following mitigation measure shall be implemented to reduce the presence of pollutants in stormwater runoff:

MM HY-6a.1 *Regulatory Stormwater Requirements. The Project Applicant shall comply with requirements of the Municipal Stormwater General Permit and associated City SWMP, appropriate performance standards established in the Green Building Ordinance, and performance standards established by the SFPUC in the San Francisco Stormwater Design Guidelines.*

The Draft San Francisco Stormwater Design Guidelines have been developed to satisfy the Municipal Stormwater General Permit requirements for new development and redevelopment projects in areas served by separate storm sewers, and are expected to be adopted by December 2009. The Project Applicant shall comply with requirements of the Draft San Francisco Stormwater Design Guidelines. Upon adoption of the Final Stormwater Design Guidelines, the Project shall comply with the Final San Francisco Stormwater Design Guidelines unless discretionary permits have been approved.

Per the Draft San Francisco Stormwater Design Guidelines, the Project Applicant shall submit a SCP to the SFPUC, as part of the development application submitted for approval. The SCP shall demonstrate how the following measures would be incorporated into the Project:

- *Low impact development site design principles (e.g., preserving natural drainage channels, treating stormwater runoff at its source rather than in downstream centralized controls)*

[599] Arup North America, Ltd., Lennar Urban, Candlestick Point/Hunters Point Shipyard LID Stormwater Opportunities Study, June, 2009. Copies of these documents are on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

- *Source control BMPs in the form of design standards and structural features for the following areas, as applicable:*
  - *Commercial areas*
  - *Restaurants*
  - *Retail gasoline outlets*
  - *Automotive repair shops*
  - *Parking lots*
- *Source control BMPs for landscaped areas shall be documented in the form of a Landscape Management Plan that relies on Integrated Pest Management[600] and also includes pesticide and fertilizer application guidelines.*
- *Treatment control measures (e.g., bioretention, porous pavement, vegetated swales) targeting the Project-specific COCs: sediment, pathogens, metals, nutrients (nitrogen and phosphorus compounds), oxygen-demanding substances, organic compounds (e.g., PCBs, pesticides), oil and grease, and trash and debris. The SCP shall demonstrate that the Project has the land area available to support the proposed BMP facilities sized per the required water quality design storm. Volume-based BMPs shall be sized to treat runoff resulting from 0.75 inches of rainfall (LEED® SS6.2), and flow-based BMPs shall be sized to treat runoff resulting from a rainfall intensity of 0.2 inches per hour. Treatment trains shall be used where feasible.*

Additional requirements:

- *LEED® SS6.2: BMPs used to treat runoff shall be designed to remove 80 percent of the average annual post-development total suspended solids loads. BMPs are considered to meet these criteria if they are designed in accordance with SFPUC requirements.*
- *The SCP shall include an Operations and Maintenance Plan that demonstrates how the treatment control BMPs would be maintained in the long term, what entities would be responsible for BMP maintenance within the public and private rights-of-way, funding mechanisms, and what mechanisms would be used to formalize maintenance and access agreements.*
- *The Project Applicant shall also prepare a Stormwater Drainage Master Plan (SDMP) for approval by the SFPUC. The SDMP shall include plans for the storm drain infrastructure and plans for stormwater management controls (e.g., vegetated swales, dry wells). The storm drain infrastructure shall illustrate conveyance of the 5-year storm event in a separate storm drain piped system, and conveyance of the 100-year storm event in the street and drainage channel rights-of-way.*

Recycled Water

Development at Candlestick Point would have to comply with the Green Building Ordinance, including the provisions of LEED® WE 1.1, which requires reducing the use of potable water for landscaping by a minimum of 50 percent. This could be met by reducing total water use for landscaping, or alternatively by using recycled water for landscaping, if such supply is available from the SFPUC.

[600] IPM is a strategy that focuses on long-term prevention or suppression of pest problems (i.e., insects, diseases and weeds) through a combination of techniques including: using pest-resistant plants; biological controls; cultural practices; habitat modification; and the judicious use of pesticides according to treatment thresholds, when monitoring indicates pesticides are needed because pest populations exceed established thresholds.

To produce and distribute recycled water, the SFPUC would have to treat the water to CCR Title 22 tertiary treatment standards and obtain coverage under the Recycled Water General Permit, which has been adopted to protect water quality standards.[601] To obtain coverage under the Recycled Water General Permit, the SFPUC would be required to submit an NOI and an Operations and Maintenance Plan to the SWRCB for approval. The Operations and Maintenance Plan would identify inspection, monitoring, and reporting requirements, and specify prohibited uses, site suitability, application rates, and salinity management measures. Compliance with the Recycled Water General Permit would ensure that the use of recycled does not cause an exceedance of water quality standards or contribute to or cause a violation of applicable waste discharge requirements.

To demonstrate compliance with the Recycled Water General Permit and the SFPUC's Operations and Maintenance Plan, the following mitigation measure shall be implemented to require preparation of a Landscape Irrigation Plan, to minimize the potential for off-site transport of pollutants in the runoff of recycled water and reduce any potential water quality impacts associated with use of recycled water for landscape irrigation.

MM HY-6a.2 *Recycled Water Irrigation Requirements. Prior to application of recycled water at the Project site for landscape irrigation, the Project Applicant shall demonstrate compliance with all terms and conditions of the SFPUC's Operations and Maintenance Plan and the Recycled Water General Permit conditions for the use of recycled water. As required by the Recycled Water General Permit, the Project Applicant shall submit an Operations and Maintenance Plan and an Irrigation Management Plan to the SWRCB. The Project Applicant shall also submit the Operations and Maintenance Plan and the Irrigation Management Plan to the SFPUC. Prior to on-site application of recycled water, the Project Applicant shall obtain written confirmation from the SFPUC that the Project Operations and Maintenance Plan and the Irrigation Management Plan is in compliance with the SFPUC's Operations and Maintenance Plan, and other SFPUC requirements for the use of recycled water.*

All recycled water provided to Project Applicant, pursuant to the Recycled Water General Permit, shall be treated in and managed in conformance with all applicable provisions of the Recycled Water Policy and shall meet Title 22 Requirements for disinfected tertiary recycled water as described in CCR Title 22, sections 60301.230 and 60301.320.

In accordance with the Recycled Water General Permit, the Project Applicant's Operations and Maintenance Plan shall describe methods and procedures for complying with recycled water regulations, and the maintenance of equipment and emergency backup systems to maintain compliance with the General Permit conditions and California Department of Public Health (CDPH) requirements. The Project Applicant shall ensure that all users of recycled water comply with the Operations and Maintenance Plan by developing educational materials (e.g., pamphlet or brochure) that convey key operational elements (e.g., prevention of cross-connections) of the plan.

In accordance with the Recycled Water General Permit, the Project Applicant's Irrigation Management Plan shall include measures to ensure the use of recycled water occurs at an agronomic rate while employing practices to minimize application of salinity constituents. The Irrigation Management Plan shall account for soil characteristics, recycled water characteristics, plant species irrigation requirements, climatic conditions, supplemental nutrient additions to support plant growth, and management of

[601] SWRCB, 2009, State Water Resources Control Board Water Quality Order No. 2009-0006-DWQ General Waste Discharge Requirements for Landscape Irrigation Uses of Municipal Recycled Water, p. 9.

impoundments used to store or collect recycled water. The Irrigation Management Plan shall describe any conditions of approval required by the City, CDPH or SWRCB.

The Project Applicant shall implement the following landscape irrigation BMPs in accordance with Recycled Water General Permit Requirements:

- *The Operations and Maintenance Plan shall include leak detection methods and correction within 72 hours of identifying a leak or prior to the release of 1,000 gallons.*
- *Recycled water shall not be applied during precipitation events.*
- *Impoundment areas shall be managed such that no discharge occurs from storms smaller than the 25-year, 24-hour event.*

The Project Applicant shall also implement BMPs for general operational controls, protection of workers and the public (e.g., education about not drinking recycled water), and efficient irrigation (e.g., dedicated landscape water meters for monitoring water usage and leak detection).

The Project Applicant shall conduct monthly monitoring to quantify the volume of recycled water applied, the locations and total area of application, and the mass of nitrogen and salinity constituents applied.

Dry Weather Flows

Dry weather flows can be generated by urban development from landscape irrigation runoff; driveway and sidewalk washing; vehicle washing; groundwater seepage; fire-fighting flows; potable water line operations and maintenance discharges; and other permitted and/or illegal non-storm water discharges.[602] Dry weather runoff is principally a water quality concern[603] as it may be a significant source of bacteria and other constituents. Dry weather flow quantities are typically estimated from monitoring data and cannot be predicted using normal hydrologic projections. The total flow volume from dry weather flow can be up to 10 to 30 percent of total runoff and dry weather flow is typically comprised of numerous small events while wet weather runoff is mainly comprised of several large events.[604,605] Drainage system capacity is typically not a concern for conveying dry weather flows.[606]

The concentrations and types of constituents in dry weather urban runoff may be different than for stormwater runoff. For example, irrigation runoff often has been shown to have higher pesticide concentrations than stormwater runoff.[607] However, long-term mean concentrations for most pollutants are likely to be lower in dry weather flows that stormwater flows.[608] Dry weather flows are typically low in sediment (TSS) because flow rates are relatively low and coarse suspended sediment tends to settle or be filtered by vegetation. Consequently, pollutants that tend to associate with suspended solids (e.g., phosphorous, some bacteria, trace metals, and pesticides) are typically found in very low concentrations in dry weather flows. Dry weather constituents are

typically dissolved constituents (e.g., nitrate, trace metals, pesticides), or constituents that are small enough to be effectively transported (e.g., pathogens and oil and grease).

Stormwater quality treatment BMPs at Candlestick Point would be implemented under the SDMP and SCP prepared pursuant to mitigation measure MM HY-6a.1. These BMPs would be permanent features at Candlestick Point and would be available year-round to capture and treat both dry weather flows and stormwater runoff and would therefore reduce pollutants that may be present in dry weather runoff. In addition, mitigation measure MM HY-6a.2, to require an Irrigation Management Plan for recycled water use, would reduce the potential for irrigation of landscaping to contribute to dry weather flows. Implementation of mitigation measures MM HY-6a.1 and MM HY-6a.2 would reduce the impact of dry weather flows on water quality to a less-than-significant level.

Summary of Impact at Candlestick Point

Compliance with applicable regulatory requirements and implementation of the mitigation measures referenced in this discussion would ensure that water quality standards would not be exceeded nor would the development at Candlestick Point cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Impact of Hunters Point Shipyard Phase II

Impact HY-6b **Implementation of the Project at HPS Phase II would not contribute to violations of water quality standards or waste discharge requirements. (Less than Significant with Mitigation) *[Criterion M.a]***

Similar to the discussion above in Impact HY-6a, development at HPS Phase II could generate stormwater runoff, which could affect water quality and could involve the use of recycled water. In addition, maritime activities associated with the proposed marina could contribute contaminants to receiving waters, which could affect water quality.

Stormwater Runoff

Development of HPS Phase II would include installation of a separate stormwater system, which would be regulated under the Municipal Stormwater General Permit. Development at HPS Phase II would remove existing land uses, including industrial and former shipyard uses that contain approximately 326.8 acres[609] of impervious surface, and replace them with new mixed land uses, including residential, commercial, office, R&D, open space, and a new football stadium, with approximately 213.7 acres[610] of impervious surfaces. Thus, implementation of HPS Phase II would reduce the area of impervious cover by approximately 35 percent. The reduction of impervious surfaces would reduce the volume of stormwater runoff from this area and the extent of impervious area that could contribute pollutants in runoff. In addition, the change in land use would affect the types and amounts of pollutants that could be present in stormwater runoff.

Table III.M-4 (Estimeated Change in Annual Pollutant Loads from HPS Phase II without BMPs) identifies the estimated change in annual pollutant loads (without the implementation of BMPs) at HPS Phase II

[609] IBI Group, August 21, 2009.
[610] IBI Group, August 21, 2009.

that would result from development. (The column for off-site residential loads represents the contributions to the on-site stormwater drainage system from HPS Phase I.) As a result of the conversion of primarily industrial lands to open space, residential, and commercial land, estimated pollutant loads would be substantially reduced by approximately 34 to 74 percent.

Table III.M-4 Estimated Change in Annual Pollutant Loads from HPS Phase II without BMPs

Pollutant	*Existing (lbs)*	*Project (lbs)*	*Difference (%)*	*Off-site Residential (lbs)*
Total Suspended Solids	304,776	113,803	-63%	*24,822*
Ammonia	625	160	-74%	*85.4*
Nitrate+Nitrite as N	1,319	864	-34%	*268*
Total Kjeldahl Nitrogen	4,026	1,133	-72%	*494*
Total Nitrogen	5,345	1,997	-63%	*762*
Dissolved Phosphorous	386	142	-63%	*68.8*
Total Phosphorous	604	235	-61%	*92.5*
Total Cadmium	1.49	0.485	-67%	*0.202*
Total Chromium	26.9	7.91	-71%	*3.32*
Total Copper	43.0	13.8	-68%	*3.63*
Total Lead	105	36.6	-65%	*17.3*
Total Nickel	18.5	9.18	-50%	*4.75*
Total Zinc	496	159	-68%	*44.6*
Fecal Coliforms (billions of colonies)	4,262,577	2,182,629	-49%	1,173,810
Stormwater Volume (acre-feet)	465.8	229.8	-40%	78.7

SOURCE: PBS&J 2009

As discussed above, mean annual pollutant loads are a function of both the concentration of pollutants, and the total amount of runoff from an area. Development at HPS Phase II would decrease the extent of impervious surfaces and therefore decrease stormwater runoff volumes (by approximately 40 percent), while changes in land use would affect the concentration of pollutants in stormwater. The net effect of these changes would be a net decrease in the total pollutants loads, even without the implementation of stormwater treatment BMPs.

Development at HPS Phase II would be required to comply with the provisions of Municipal Stormwater General Permit and the associated SWMP, the Draft San Francisco Stormwater Design Guidelines, and San Francisco Green Building Ordinance. Consistent with these requirements, the Project Applicant would be required to submit a SDMP and SCP to the SFPUC, which would identify the specific stormwater treatment BMPs that would be implemented. To minimize the potential for stormwater pollutants to adversely affect water quality, mitigation measure MM HY-6-a.1 would be implemented.

As discussed above, although the specific BMPs that will be implemented have yet to be identified, the stormwater LID Study identified various stormwater treatment opportunities. However, the use of infiltration BMPs on the HPS Phase II site would be precluded by site constraints related to soil and

physical characteristics and the presence of contaminants in soil associated with historic land uses. Further, the potential for stormwater BMPs to result in the mobilization of historic contaminants in soil would be reduced by the placement of fill soils in various locations to raise the land surface above the base-flood elevation (as discussed in Section III.L), thus increasing the height of soil cover in those locations.

Prior to the transfer of the HPS Phase II site, all necessary remedial actions at HPS Phase II required by CERCLA, the FFA, or other applicable law, must be completed to the satisfaction of the relevant regulatory agencies, and those agencies must determine that the site is suitable for its intended use. The Navy would implement Institutional Controls (ICs) for cleanup at HPS Phase II. These IC's are legal and administrative mechanisms to implement land use restrictions to limit the exposure of future landowners and users to hazardous materials, and to ensure the integrity of remedial activities. The mitigation measures set forth in Section III.K require compliance with these requirements. Mitigation measure MM HZ-1b would require the San Francisco Department of Public Health to verify, before any development activity occurs at HPS Phase II, that remediation as been completed in compliance with all restrictions imposed for the site. Mitigation measure MM HZ-2a.1 (Unknown Contaminant Contingency Plan) would ensure that potential risks associated with unknown contamination sites are minimized. Mitigation measures MM HZ-5a (Foundation Support Piles Installation Plan), MM HZ-9 (Navy-Approved Workplans for Construction and Remediation Activities on Navy-Owned Property), MM HZ-10b (Regulatory Agency-Approved Workplans and Permits for Shoreline Improvements), and MM HZ-12 (Compliance with Administrative Order of Consent at Early Transferred Parcels), and MM HZ-15 (Asbestos Dust Mitigation and Control Plans) also include measures to protect water quality. With these mitigation measures, the potential for historic soil contamination to be mobilized by stormwater runoff would be minimized.

Although open spaces at HPS, Phase II would capture rainfall which could percolate into the soil, compliance with mitigation measures identified above would reduce the potential for mobilization of contaminants in soil from historic uses. The use of stormwater infiltration BMPs, which would enhance percolation of runoff, could increase the potential for mobilization of soil contaminants. To reduce this potential, mitigation measure MM HY-6b.1 would prohibit use of infiltration BMPs and require lined stormwater conveyance systems at HPS Phase II to protect groundwater quality.

MM HY-6b.1 *Limitations on Stormwater Infiltration: Infiltration BMPs on HPS Phase II shall be prohibited. Alternative BMPs for stormwater quality control, reuse, and treatment shall be used. For instance, biofiltration BMPs can be implemented with an impervious liner and subdrain system to treat stormwater runoff while preventing infiltration. Overland flow (greater than the five-year and up to the 100-year storm) shall be conveyed in lined channels or other conveyances that will not result in infiltration.*

Stormwater from Industrial Activities

HPS Phase II development would include R&D space within certain areas and some potential uses within this land use category could be considered industrial activities for the purposes of a stormwater permit. Any such industrial uses would be required to obtain coverage under the Industrial General Permit for stormwater discharges. Implementation of mitigation measure MM HY-6b.2 would ensure compliance with the Industrial General Permit, as necessary, which would require the development and implementation of an industrial SWPPP to reduce potential impacts.

MM HY-6b.2 *Industrial General Permit: The Facility Operator shall apply for an Industrial General Permit prior to operational activities for facilities requiring coverage under the Industrial General Permit, which is determined based on the facility's SIC. The Facility Operator shall comply with all provisions in the Industrial General Permit, including implementation of a SWPPP, to effectively control pollutants to the BAT/BCT during the normal course of operations. Primary components and pollution prevention measures that the SWPPP shall address are described below. The Facility Operator shall refer to the California Stormwater Quality Association Stormwater Best Management Practice Handbook – Industrial and Commercial or equivalent[611] for details on BMP implementation. The SFRWQCB is responsible for overseeing Industrial General Permit activities, including SWPPP compliance. The following BMPs shall be incorporated into the SWPPP.*

Non-Structural BMPs

- *Good Housekeeping: Good housekeeping generally consists of practical procedures to maintain a clean and orderly facility.*
- *Preventive Maintenance: Regular inspection and maintenance of structural stormwater controls (catch basins, oil/water separators, etc.) as well as other facility equipment and systems.*
- *Spill Response: Spill clean-up procedures and necessary clean-up equipment based upon the quantities and locations of significant materials that may spill or leak.*
- *Material Handling and Storage: Procedures to minimize the potential for spills and leaks and to minimize exposure of significant materials to stormwater and authorized non-stormwater discharges.*
- *Employee Training: Training of personnel who are responsible for (1) implementing activities identified in the SWPPP, (2) conducting inspections, sampling, and visual observations, and (3) managing stormwater. The SWPPP shall identify periodic dates for such training. Records shall be maintained of all training sessions held.*
- *Waste Handling/Recycling: Procedures or processes to handle, store, or dispose of waste materials or recyclable materials.*
- *Recordkeeping and Internal Reporting: Procedures to ensure that all records of inspections, spills, maintenance activities, corrective actions, visual observations, etc., are developed, retained, and provided, as necessary, to the appropriate facility personnel.*
- *Erosion Control and Site Stabilization: This may include the planting and maintenance of vegetation, diversion of run-on and runoff, placement of sandbags, silt screens, or other sediment control devices, etc.*
- *Inspections: This includes, in addition to the preventative maintenance inspections identified above, an inspection schedule of all potential pollutant sources. Tracking and follow-up procedures shall be described to ensure adequate corrective actions are taken and SWPPP revisions are made as needed.*
- *Quality Assurance: Procedures to ensure that all elements of the SWPPP and Monitoring Program are adequately conducted.*

Structural BMPs to be Considered

- *Overhead Coverage: Structures that provide horizontal coverage of materials, chemicals, and pollutant sources from contact with stormwater and authorized non-stormwater discharges.*

[611] California Stormwater Quality Association, Stormwater Best Management Practice Handbook- Industrial and Commercial, January, 2003.

- *Retention Ponds: Basins, ponds, surface impoundments, etc. that do not allow stormwater to discharge from the facility.*
- *Control Devices: Berms or other devices that channel or route run-on and runoff away from pollutant sources.*
- *Secondary Containment Structures: This generally includes containment structures around storage tanks and other areas for the purpose of collecting any leaks or spills.*
- *Treatment: This includes inlet controls, infiltration devices, oil/water separators, detention ponds, vegetative swales, etc. that reduce the pollutants in stormwater discharges and authorized non-stormwater discharges. However, because of extensive site constraints, use of infiltration BMPs shall be limited.*

Recycled Water

As discussed above, under Impact HY-6a, the HPS Phase II may use recycled water from the SFPUC for landscaping to reduce potable water demand. Compliance with the Recycled Water General Permit would ensure that the use of recycled does not cause an exceedance of water quality standards or contribute to or cause a violation of applicable waste discharge requirements. The Operations and Maintenance Plan would identify inspection, monitoring, and reporting requirements, and specify prohibited uses, site suitability, application rates, and salinity management measures. The Irrigation Management Plan would demonstrate how the water is used effectively and what practices would be used to minimize application of salinity constituents. Mitigation measure MM HY-6a.2 would be implemented to ensure compliance with the Recycled Water General Permit and the SFPUC's Operations and Maintenance Plan for recycled water.

Dry Weather Flows

As discussed above, dry weather flows can be generated by urban development and have the potential to affect receiving water quality. Consistent with regulatory requirements, stormwater treatment BMPs would be implemented under the SDMP and SCP for wet weather runoff (per mitigation measure MM HY-6a.1) and these measures would also capture and treat dry weather flows. Mitigation measure MM HY-6a.2 would be implemented to reduce the potential discharge of polluted runoff from landscape irrigation with recycled water. Compliance with these requirements would ensure that the dry weather flows do not cause an exceedance of water quality standards or contribute to or cause a violation of applicable waste discharge requirements.

Marina Operations

Dredging

Development of the marina would include creation of two basins (by means of constructing breakwater in the Bay to form one 11.3 basin and one 10.7 basin) that would not require initial dredging, but may require ongoing maintenance dredging in the future. Dredging activities could result in the re-suspension of previously undisturbed in-Bay sediments, which could adversely affect water quality.[612] In-water disposal of dredge spoils has the potential to alter benthic and shoreline habitats and to increase water column turbidity.[613] The potential for maintenance dredging to result in impacts to Biological Resources is discussed

[612] San Francisco Estuary Institute (SFEI), Effects of Short-term Water Quality Impacts due to Dredging and Disposal on Sensitive Fish Species in San Francisco Bay, Prepared for Corps San Francisco District, 2008.
[613] California Regional Water Quality Control Board San Francisco Bay Region, 2007, op. cit.

in Section III.N; refer to mitigation measures MM BI-18b.1 (Maintenance Dredging and Turbidity Minimization Measure for the Operation of the Marina), MM BI-18b.2 (Implement BMPs to Reduce Impacts of Dredging to Water Quality), MM BI-19b.1 (Work Windows to Reduce Maintenance Dredging Impacts to Fish during Operation of the Marina), and MM BI-19b.2 (Implement BMPs to Reduce Impacts of Dredging to Water Quality). Compliance with applicable DMMO regulatory requirements would ensure that maintenance dredging operations do not cause an exceedance of water quality standards or contribute to or cause a violation of applicable waste discharge requirements. Implementation of these mitigation measures would reduce the water quality impacts from marina dredging and a less than significant impact would result.

Operational Discharges

The discharge of stormwater runoff from the marina would be regulated under the Municipal Stormwater General Permit, which would require the preparation of a SDMP and SCP, consistent with mitigation measure MM HY-6-a.1.

In addition, the marina operator would be required to obtain certification of by the Clean Marinas California Program to reduce potential water quality affects associated with marina operations. To ensure compliance with these requirements, mitigation measure MM HY-6b.3 would be implemented.

MM HY-6b.3 *Clean Marinas California Program: The marina operator shall obtain certification under the Clean Marinas California Program. The Clean Marinas California Program has developed marina BMPs and an inspection and certification process for marinas that meet the program standard for BMP implementation. The marina operator shall implement BMPs that address the following sources of pollution: petroleum containment, topside boat maintenance and cleaning, underwater boat hull cleaning, marina operations, marina debris, boat sewage discharge, solid waste, liquid waste, fish waste, hazardous materials, and stormwater runoff.*

No fueling facilities are proposed as part of marina operations. However, if maintenance activities such as rehabilitation, mechanical repairs, painting, and lubrication or equipment cleaning operations are conducted, stormwater runoff from the marina would also be regulated under the Industrial General Permit. Compliance with the requirements of the Industrial General Permit (for applicable portions of the marina, if any) would reduce potential water quality impacts. Implementation of mitigation measure MM HY-6b.2 (to obtain coverage under the Industrial General Permit) would ensure compliance with the requirements for any maintenance operations.

Summary of Impact at Hunters Point Shipyard, Phase II

Compliance with applicable regulatory requirements and implementation of all of the mitigation measures referenced in this discussion would ensure that water quality standards would not be exceeded nor would the development at HPS Phase II cause or contribute to a violation of the applicable WDRs. A less-than-significant impact would result.

Impact of Yosemite Slough Bridge

Impact HY-6c **Implementation of the Yosemite Slough bridge would not contribute to violations of water quality standards or waste discharge requirements. (Less than Significant) *[Criterion M.a]***

Stormwater runoff from the Yosemite Slough bridge and discharges of materials from bridge maintenance activities would not cause or contribute to an exceedance of water quality standards. Primary pollutants of concern in stormwater runoff from transportation-related land uses include fuels, PAHs, sediment, metals, and litter and debris. The pollutants could originate from automobiles, transit vehicles, cyclists, and pedestrians. Automobiles would only be a source of stormwater pollutants on game days, which occur twelve days out of the year, because the bridge would only allow automobile traffic on game days. As described in Chapter II (Project Description) on page II-38, the Yosemite Slough bridge would be constructed with a 40-foot-wide greenway, which would be converted to automobile travel lanes on 49ers game days only. The greenway would also provide vegetative treatment for stormwater pollutants associated with automobiles, and would reduce the impacts of automobile-related stormwater runoff to a less than significant level. Runoff from the transit vehicle lanes would also be routed to the greenway and/or to land-based stormwater treatment controls such as swales. The stormwater treatment measures for the bridge would be described in the Project's Stormwater Control Plan, which is subject to SFPUC's approval.

Bridge maintenance activities such as welding and grinding, sandblasting, and painting can also adversely affect water quality if materials generated from maintenance are allowed to discharge into the Bay. It is anticipated that bridge operation would be under the jurisdiction of the City, and thus stormwater runoff mitigation would be performed under the Municipal Stormwater General Permit, which requires development of a pollution prevention program for municipal operations. The municipal operations program would also include street sweeping to remove litter and sediment-associated pollutants generated by transportation land uses.

Pollutants generated from transit vehicles, cyclists and pedestrians would also be addressed under the pollution prevention program for municipal operations implemented by the City. The pollutants would also be reduced through compliance with local stormwater treatment requirements (i.e., San Francisco Stormwater Design Guidelines), which were put into effect to comply with the new development requirements in the Municipal Stormwater General Permit.

Impacts from bridge operation would be reduced via compliance with the existing stormwater runoff programs, specifically, elements of the Municipal Stormwater General Permit, and local requirements for stormwater treatment measures that would be subject to approval by the SFPUC. Operation of the Yosemite Slough bridge would not cause an exceedance of water quality standards or contribute to or cause a violation of waste discharge requirements and a less than significant impact would result. No mitigation is required.

Combined Impact of Candlestick Point, Hunters Point Shipyard Phase II, and Yosemite Slough Bridge

Impact HY-6 **Implementation of the Project would not contribute to violations of water quality standards or waste discharge requirements. (Less than Significant with Mitigation) *[Criterion M.a]***

As discussed in Impact HY-6a through Impact HY-6c, compliance with the requirements of the Municipal Stormwater General Permit, the Recycled Water General Permit, and the Industrial General Permit would reduce potential water quality impacts associated with implementation of the Project. In addition, the project would be required to comply with the San Francisco SWMP, the Draft San Francisco Stormwater Design Guidelines, and the San Francisco Green Building Ordinance. Compliance with these requirements would be demonstrated in the SDMP or SCP for the project site, as required by mitigation measure MM HY-6a.1. Compliance with the Recycled Water General Permit would be required by implementation of mitigation measure MM HY-6a.2. To reduce the potential for stormwater infiltration to mobilize historic soil contaminants at HPS Phase II, the use of infiltration BMPs would be prohibited by mitigation measure MM HY-6b.1. To reduce stormwater runoff impacts associated with industrial activities at HPS Phase II, compliance with the Industrial General Permit would be required by implementation of mitigation measure MM HY-6b.2. To reduce stormwater impacts associated with maintenance dredging of the marina, compliance with the DMMO regulatory requirements would be required by implementation of mitigation measures MM BI-18b.1 (Maintenance Dredging and Turbidity Minimization Measure for the Operation of the Marina), MM BI-18b.2 (Implement BMPs to Reduce Impacts of Dredging to Water Quality), MM BI-19b.1 (Work Windows to Reduce Maintenance Dredging Impacts to Fish during Operation of the Marina), and MM BI-19b.2 (Implement BMPs to Reduce Impacts of Dredging to Water Quality). Compliance with the Clean Marinas California Program would be required by implementation of mitigation measure MM HY-6b.3. Compliance with applicable regulatory requirements and implementation of the identified mitigation measures would ensure the Project would not cause an exceedance of water quality standards or contribute to or cause a violation of waste discharge requirements and a less than significant impact would result.

Impact HY-7: Other Water Quality Effects

Impact HY-7 **Implementation of the Project would not otherwise degrade water quality. (Less than Significant with Mitigation) *[Criterion M.f]***

Stormwater and recycled water infiltration to groundwater could degrade groundwater quality. One of the Project's stormwater management strategies includes infiltration of stormwater runoff in Candlestick Point, where feasible, using permeable pavement, bioretention basins and other measures, to control peak flow rates, reduce total runoff volumes, and reduce the potential quantity of pollutants in residual surface runoff. Urban stormwater runoff contains a variety of pollutants that could potentially reach groundwater aquifer via infiltration. Research on groundwater effects resulting from stormwater infiltration indicate that the potential for groundwater contamination via infiltration depends on several pollutant- and site-specific environmental factors such as: (1) precipitation, irrigation, dry weather runoff, and temperature patterns;

(2) soil properties such as texture; clay content, mineral content, organic matter and microbial content; and presence of structural voids; and (3) depth to the groundwater table.[614]

Chemical characteristics of the potential stormwater COCs and recycled water constituents that could infiltrate to groundwater aquifer include (1) mobility (measured by parameters such as solubility, sorption coefficients, and vapor pressure) and persistence (measured by the half-life) in soil; (2) use patterns; and (3) abundance in stormwater and dry weather runoff.

Some stormwater pollutants such as metals, certain pesticides and herbicides, and pathogens tend to be filtered out by soils and have a low probability of leaching into groundwater. More mobile chemicals such as nitrate and other dissolved constituents (e.g., chemicals that contribute to total dissolved solids [TDS] such as chloride), have a greater potential for leaching into groundwater. Groundwater in portions of the Project site has been impacted by releases of various inorganic and organic constituents associated with current and previous land uses, and a remediation program is ongoing. DWR also indicates that elevated nitrate concentrations are the most common water quality problem with wells in the San Francisco Peninsula. Data from the National Stormwater Quality Database[615] indicate that stormwater runoff from land uses similar to the Project (e.g., mixed residential, commercial and industrial) has a total dissolved solids (TDS) concentration of about 80 mg/L and a nitrate (as nitrogen) concentration of about 0.6 mg/L; these concentrations would not be expected to adversely affect groundwater quality. Use of recycled water could increase groundwater salinity because recycled water tends to concentrate salts and have a higher salt content than potable water. However, the underlying groundwater basins are only designated as potential municipal or domestic water supplies. As such, there are no applicable water quality standards.

Implementation of mitigation measure MM HY-6a.1 would ensure compliance with the Municipal Stormwater General Permit, which would result in BMPs designed to treat stormwater runoff for nitrogen compounds and limit infiltration BMPs at Candlestick Point where site physical constraints (e.g., shallow depth to groundwater) are present. Limitations on infiltration BMPs would reduce the potential for nitrate and TDS leaching to groundwater. Mitigation measure MM HY-6b.1 would prohibit infiltration BMPs at HPS Phase II and further reduce the potential for nitrate and TDS degradation of groundwater quality underlying HPS Phase II. Implementation of mitigation measure MM HY-6a.2 would ensure compliance with the Recycled Water General Permit, resulting in application rates that do not exceed agronomic requirements. As such, the potential for recycled water, and associated nitrates and TDS, leaching to groundwater is minimized. Compliance with these mitigation measures would reduce the potential for nitrogen and salt migration to groundwater and Project degradation of groundwater quality would be less than significant.

Impact HY-8: Groundwater Supplies and Groundwater Recharge

Impact HY-8 **Implementation of the Project would not substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level. (No Impact) *[Criterion M.b]***

The Project would not use groundwater as a source of water supply, and would, therefore, not deplete groundwater supplies. The Project site is currently primarily impervious surfaces and would not, therefore, substantially contribute to groundwater recharge. The Project would remove existing structures, including Alice Griffith Housing, Candlestick Park stadium, and the parking lots surrounding the stadium which include approximately 178.5 acres[616] of impervious surfaces. The proposed development of new mixed land uses at Candlestick Point would include residential, commercial, office, and recreational uses, which could include approximately 165.4 acres[617] of impervious surfaces. Development at Candlestick Point would result in an approximate 7 percent decrease in impervious surfaces, which could increase infiltration. At HPS Phase II, the Project would remove existing improvements, including industrial and former shipyard uses that contain approximately 326.8 acres[618] of impervious surfaces. The proposed development at HPS Phase II consisting of new mixed land uses, including residential, commercial, office, R&D, open space, and a new football stadium, would result in approximately 213.7 acres[619] of impervious surfaces. Thus, implementation of HPS Phase II would decrease the impervious cover of the HPS Phase II area by approximately 35 percent, which could increase infiltration (via natural percolation of rainfall, as stormwater infiltration BMPs would be prohibited by mitigation measure HY-6b.1). Overall, development of the Project would result in a decrease in impervious surfaces of approximately 25 percent. By decreasing the extent of impervious cover and by limiting stormwater infiltration BMPs to Candlestick Point, development at the Project would not interfere with groundwater recharge or substantially deplete groundwater supplies, and thus no impact would occur. No mitigation is required.

Impact HY-9: Erosion or Siltation Effects

Impact HY-9 **Implementation of the Project would not alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, and would not result in substantial erosion or siltation on site or off site. (Less than Significant with Mitigation) *[Criterion M.c]***

As discussed above in Constructions Impacts, Project grading would not substantially alter the drainage pattern of the site. Off-site erosion or siltation impacts from new development can occur in the form of stream channel hydromodification,[620] caused by increased impervious cover that increases stormwater peak

[616] IBI Group, August 21, 2009.
[617] Ibid.
[618] IBI Group, August 21, 2009.
[619] Ibid.
[620] Hydromodification refers to the change in the stream flow hydrograph (e.g., flow rate, timing of peak flows, flow duration, and flow volume). Stream channels are formed as a function of the water flow patterns (hydrograph). When patterns change (e.g., changes in runoff to the stream), the channel form (e.g., depth, width, curvature, substrate) and function (e.g., habitat quality, habitat area) can be altered as beds and banks erode (or build up) in response to the change in flow regime.

flow rates, volumes, and durations into a water body susceptible to bed or bank erosion. The Project site would discharge to separate sewer systems or the Lower Bay, rather than surface water bodies susceptible to erosion and siltation. There are no streams or rivers at the Project site and the Project would not discharge directly or indirectly to a stream or river. Therefore, no impacts to streams or rivers would occur. Although some areas would continue to sheet flow to the Lower Bay, these areas would not receive additional flows from the developed portion of the Project site and the potential for increased erosion and sediment transport would be less than significant. In addition, implementation of mitigation measure MM HY-6a.1would require preparation of a SDMP and SCP to control post-construction erosion that incorporates erosion and sediment transport control BMPs. A less-than-significant impact would occur.

Impact HY-10: Flooding From Surface Runoff[621]

Impact HY-10 **Implementation of the Project would not alter the existing drainage pattern of the site, through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff, and would not result in flooding on site or off site. (Less than Significant with Mitigation)** ***[Criterion M.d]***

The Project would remove existing structures and uses at Candlestick Point, including Alice Griffith Housing, Candlestick Park stadium, and the parking lots surrounding the stadium which total approximately 178.5 acres[622] of impervious surface area. Proposed new land uses at Candlestick Point would include residential, commercial, office, and recreational uses, which would total approximately 165.4 acres[623] of impervious surface. Thus, development at Candlestick Point would reduce the area of impervious surfaces. The Project would also remove existing structures and uses at HPS Phase II, including industrial and former shipyard features that total approximately 326.8 acres[624] of impervious surface area. Proposed uses at HPS Phase II, including residential, commercial, office, R&D, open space, and a new football stadium, would total approximately 213.7 acres[625] of impervious surface area. Thus, implementation of HPS Phase II would also reduce the amount of impervious cover at HPS Phase II. Because of the increase in permeable surface area, infiltration would be expected to increase, resulting in a corresponding decrease in runoff volumes. Grading would reduce slopes at both sites, slowing runoff rates.

- The runoff flow rates and volumes do not account for the effect of Project BMPs.

- Table III.M-5 (Estimated Existing and Project Stormwater Peak Flow Rates and Runoff Volumes without BMPs) lists the estimated Project site stormwater runoff flow rates for existing and Project conditions, calculated using the Rational Method.[626] Details on flow rate calculations are provided in Appendix M1. For HPS Phase II, flow rates reported in Table III.M-5 do not include off-site flow from HPS Phase I. The City has required the HPS Phase II development to convey the 5-year storm event from HPS Phase I in the

[621] As discussed in the Setting, the Project site is not currently subject to flooding from a stream or river. Tidal flooding is discussed under Impacts HY-12a, 12b, 12, 13a, 13b, 13, and 14.

Project storm drain system (108 cfs of flow for the 5-year storm event) in addition to Project flows. However, HPS Phase I flows are existing flows, currently draining to the separate storm system. Therefore, although these flows must be accounted for in the sizing of Project storm drain infrastructure, they are not included in Table III.M-5 because they are not Project site flows and are not affected by development of the Project.

Table III.M-5 Estimated Existing and Project Stormwater Peak Flow Rates and Runoff Volumes without BMPs

			Project Increase[a]	
Storm Event	*Existing (cfs)[b]*	*Project (cfs)[c]*	*(cfs)*	*(%)*
Candlestick Point				
5-Year	477 (130)[d]	249 (0)[d]	-228	-48%
10-Year	545	284	-261	-48%
100-Year	783	408	-375	-48%

5-Year	644	448	-196	-30%
10-Year	730	509	-221	-30%
100-Year	1052	733	-319	-30%
2-year 24-hour (acre-feet)				
Candlestick Point	36	20	-16	-44%
HPS Phase II	64	39	-24	-38%

SOURCE: PBS&J 2009

a. A negative number denotes a reduction in Project flow rates compared to existing conditions.
b. Existing flows are based on 72 percent impervious surfaces (505.3 acres).
c. Project flows are based on 54 percent impervious surfaces 9379.1 acres).
d. Values in parenthesis denote the amount of total Candlestick Point site runoff flowing to the combined sewer system.
e. Off-site flow from HPS Phase I is not included in these runoff calculations. Required HPS Phase I diversions into the HPS Phase II separate stormwater sewer system would be 108 cfs.

As demonstrated in Table III.M-5, the runoff peak flow rates from the Project site would be reduced by an average of 39 percent. Although these calculations are based on estimated site characteristics, it is not likely that more detailed data would indicate a substantially lower peak flow rates. Table III.M-5 also shows that runoff volumes from the 2-year 24-hour storm (i.e., frequently occurring storms) would be reduced by implementation of the Project, which would also reduce flooding impacts.

Grading and fill placement would be required to bring surface elevations to a level appropriate for development (i.e., a level that would not be subject to flooding and that would support Project structures). Material removed from Candlestick Point would be used for embankments at HPS Phase II. The overall drainage pattern (runoff into a piped system for the majority of the Project site and sheet flow into the Lower Bay for remaining portions) would be preserved following development,[627] and no rivers or streams exist on site that would be altered by development. Most of the Project site would be graded with a 0.1 percent slope to facilitate overland flow, and the streets would have a waffling grade[628] of 0.5 percent to

[627] MACTEC Engineering and Consulting, Inc., *Proposed Infrastructure Plans and Implementation Schedule, Hunters Point/Candlestick Point Redevelopment Project,* Draft, July 7, 2008. [628] A surface texture marked by ridges and valleys that would help to channel flow.

reduce localized stormwater ponding.[629] According to the City, new developments must ensure that stormwater runoff volumes, up to the volumes anticipated for a five-year storm event, would be adequately conveyed in pipes.[630] Storms larger than the five-year storm and up to the 100-year storm event should be conveyed adequately via overland flow, i.e., through street gutters and swales. The design objective for overland flow is to allow streets and sidewalks to fully contain the 100-year event without surcharging[631] (flooding) the adjacent development blocks.[632] Downstream flooding would not occur because the Project is directly upstream of the Bay.

As discussed in Impact HY-6a, p. III.M-114, the Project Applicant has developed a LID Study,[633] which identifies concepts for how the development could integrate stormwater volume reduction and treatment control measures. Mitigation measure MM HY-6a.1 would require preparation, and SFPUC approval, of a SDMP and SCP for the Project that would ensure that this impact is less than significant.

Impact HY-11: Storm Sewer System Capacity

Impact HY-11 **Implementation of the Project would not create or contribute runoff water that would exceed the capacity of existing or planned storm sewer systems or provide substantial additional sources of polluted runoff. (Less than Significant with Mitigation) *[Criterion M.e]***

A new separate storm sewer system would be constructed at the Project site in accordance with the design standards and criteria issued by the SFPUC and criteria in the San Francisco Subdivision Regulations.[634] The capacity design basis in those regulations specify that storm sewers should have sufficient capacity, when flowing full or surcharged (flow in manholes is above top of pipe), to carry the estimated stormwater runoff from the 5-year storm event, based on the ultimate development of the area, including natural drainage from upstream areas. Flows up to the five-year storm event would be carried in pipes, and larger flows, up to the 100-year storm, would be conveyed via overland flow, street rights-of-way, drainage channels, and pipes. As discussed in Impact HY-10, above, overall Project site development would result in an average of approximately 39 percent reduction in peak storm flows and would also reduce runoff volumes from frequently occurring storms. Implementation of mitigation measure MM HY-6a.1 and compliance with stormwater drainage capacity design criteria would ensure that impacts related to exceeding the capacity of the storm sewer system would be less than significant.

Impact HY-12: Housing within a 100-Year Flood Hazard Area

Impact of Candlestick Point

Impact HY-12a **Implementation of the Project at Candlestick Point would not place housing in a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map. (Less than Significant with Mitigation) *[Criterion M.g]***

SFHAs shown on the preliminary FIRM for San Francisco and the Interim Floodplain Map are indicated in Figure III.M-4. Residential development at Candlestick Point could be placed within the area currently designated as Zone A.

The preliminary grading plan for Candlestick Point598 shows that the site would be graded such that the finished grade would be 3 feet higher than the Base Flood Elevation, and building finish floors would be 6 inches above that (total of 42 inches above Base Flood Elevation) per MM HY-12a.1 (Figure III.M-7 [Existing Flood Zones and Sea Level Rise [with Project Land Use Overlay and with Project Shoreline and Grading Improvements]). The Project grading plans indicate bayside elevations of +2.0 feet SFCD. The 100-year flood elevation with a 36-inch sea level rise would be +1.2 feet SFCD. Therefore, according to the current grading plan, development of Candlestick Point would be above the 100-year flood elevation with a safety factor of 36 inches to allow for future sea level rise.

Mitigation measure MM HY-12a.1 requires the Project Applicant to ensure that all finished grade elevations would be above the Base Flood Elevation and to request revision of the San Francisco Interim Floodplain Maps (or FIRMs, if adopted prior to Project implementation) to reflect new fill.

Implementation of mitigation measure MM HY-12a.1 would ensure that impacts associated with construction of housing within a 100-year flood hazard area, as designated on a flood hazard delineation map, would be less than significant.

MM HY-12a.1 *Finished Grade Elevations Above Base Flood Elevation. The Project site shall be graded such that finished floor elevations are 3.5 feet above the Base Flood Elevation (BFE), and streets and pads are 3 feet above BFE to allow for future sea level rise, thereby elevating all housing and structures above the existing and potential future flood hazard area. If the FIRM for San Francisco is not finalized prior to implementation of the Project, the Project Applicant shall work with the City Surveyor to revise the City's Interim Floodplain Map. If the FIRM for San Francisco is finalized prior to implementation of the Project, the Project Applicant shall request that the Office of the City Administrator (Floodplain Manager) request a Letter of Map Revision based on Fill (LOMR-F) from FEMA that places the Project outside a SFHA and requires that the FIRM is updated by FEMA to reflect revised regulatory floodplain designations.*

Rising sea levels is an ongoing phenomenon, which needs to be accounted for in the planning process to prevent future flooding or loss of infrastructure due to shoreline erosion. Planning for sea level rise includes three separate components (1) designing the perimeter to be flexible enough that crest elevations could be increased to prevent overtopping, (2) designing the development areas to be high enough that flooding would not occur around dwellings should the perimeter not function adequately, (3) designing the storm drainage system to be flexible enough that higher water levels would not result in overland flooding. It is obvious that while the perimeter and storm drain system could be upgraded over time, habitable structures cannot be raised.

PBS&J 11.2.09 08068 | JCS | 09

FIGURE III.M-7

Candlestick Point — Hunters Point Shipyard Phase II EIR

EXISTING FLOOD ZONES AND SEA LEVEL RISE (WITH PROJECT LAND USE OVERLAY AND WITH PROJECT SHORELINE AND GRADING IMPROVEMENTS)

There is no current guidance or policy establishing numeric values for development projects along the Bay edge. The Federal Emergency Management Agency (FEMA) maps flood zones based on present day rainfall and tidal conditions, but regional and local agencies have taken a more proactive approach in reviewing development proposals because of the public infrastructure element for which they would be responsible.

A project specific sea level rise study was undertaken[635] to develop planning and design guidance through the various phases of the project. The study was based on an exhaustive review of the literature, recent guidance from regional agencies, and knowledge of coastal processes of San Francisco Bay. The literature on sea level rise estimates varies widely, from an observed value of 8 inches per century (historical measurements) to 33 inches per century (Intergovernmental Panel on Climate Change [IPCC] maximum estimate). News articles and semi-empirical studies (Rahmstorf 2007) based in part on recent measurements of ice cap melt, have stated that the increase in sea level rise over the next 100 years could be much higher than those estimated by the Intergovernmental Panel on Climate Change. Even among projections considered plausible, albeit high, by the CALFED Independent Science Board, a sea level rise of 36-inches would not occur until about 2075 to 2080 and by about 2100 the sea level rise could reach 55 inches. However, sea level observations since the publication date of the ice cap melt studies, although not conclusive to establish a new trend in sea level rise, do not show the accelerated sea level rise trajectory predicted by some of the reports.[636]

Project design for sea level rise meets both near term (2050) and long-range (2080) objectives; and in addition, incorporates an adaptive management strategy to address sea level rise for the most conservative estimates at 2100 and beyond. Since building structures are generally "immovable", whereas a perimeter and/or storm drain system can be adapted to keep up with changing sea levels, each was designed to a specific planning horizon as described below.

Development Design

For building structures, a 36-inch sea level rise allowance plus a freeboard of 6 inches was selected as the design criteria to use for design and construction. Per the most conservative rate of sea level rise (Rahmstorf 2007, which includes ice-cap melt estimate), a sea level rise of 36 inches would not occur until about 2080,[637] which would be approximately 50 years beyond the last phase of construction for the project. Ongoing measurements of sea level rise from the scientific community would be incorporated into Monitoring and Adaptive Management Plans, administered by a Geologic Hazard Abatement District (GHAD) or other entity with similar funding responsibility.[638] This entity would guide the decision-making process for implementation of future improvements, such as raising the perimeter. The proposed Monitoring and Adaptive Management Plan for the project would have the appropriate language that specifies management actions that would need to occur should sea level rise exceed 36 inches. Should sea level rise exceed 36 inches, the proposed project-specific funding mechanism (GHAD or similar) would pay for improvements.

636 Rahmstorf, S., A. Cazenave, J.A. Church, J.E. Hansen, R.F. Keeling, D.E. Parker, and R.C.J. Somerville, 2007. *Recent Climate Observations Compared to Projections*. Science 316, p. 709.
637 Moffatt & Nichol, *Candlestick Point/Hunters Point Development Project Initial Shoreline Assessment*, prepared for Lennar Urban, February, 2009, op. cit.
638 Moffatt & Nichol, *Hunters Point Shoreline Structures Assessment*, October 2009.

Perimeter and Storm System Design

For the perimeter system, it is not practical to build a high wall around the project for a design condition that may not happen for several decades. At the same time, it is not prudent to build to present sea level conditions and keep raising it as sea levels rise. Therefore, an interim sea level rise estimate for the year 2050, as put forth by BCDC and the State Coastal Conservancy,[639] was selected as the design criteria to use for design and construction. That sea level is 16 inches higher than the present, which will ensure that adaptive management construction activities are not triggered until at least the year 2050. In addition, the shoreline and public access improvements have been designed with a development setback to allow any future increases in elevation to accommodate higher sea level rise values, should they occur.

For the storm drain system, the same approach as the perimeter system described above was adopted. This will avoid installing pumps and other appurtenances at the present time, when they are not needed, while still ensuring that an adaptation strategy and a funding mechanism exists for future management actions.

Mitigation measure MM HY-12a.2 would require open space setbacks along the shoreline to allow for additional fill if the rate of future sea level rise is more rapid than currently anticipated. Implementation of mitigation measure MM HY-12a.2 would ensure flooding impacts associated with more rapid sea level rise would remain at a less-than-significant level.

- *MM HY-12a.2* *Shoreline Improvements for Future Sea-Level Rise. Shoreline and public access improvements shall be designed to allow future increases in elevation along the shoreline edge to keep up with higher sea level rise values, should they occur. Design elements shall include providing adequate setbacks to allow for future elevation increases of at least 3 feet from the existing elevation along the shoreline. Before the first Small Lot Final Map is approved, the Project Applicant must petition the appropriate governing body to form (or annex into if appropriate) and administer a special assessment district or other funding mechanism to finance and construct future improvements necessary to ensure that the shoreline, public facilities, and public access improvements will be protected should sea level rise exceed 16 inches at the perimeter of the Project. Prior to the sale of the first residential unit within the Project, the legislative body shall have acted upon the petition to include the property within the district boundary. The newly formed district shall also administer a Monitoring and Adaptive Management Plan to monitor sea level and implement and maintain the protective improvements.*

To guide the storm drain system design and establish the perimeter crest elevation, recent guidance from the Climate Change Center[640] and the policies adopted by the California State Coastal Conservancy[641] of using a 16-inch sea level rise by the year 2050 for a planning horizon were used. The storm drain system will, thus, function as a gravity-drained system up to the year 2050 and not require any management action until that point in time. Beyond the 16-inch sea level rise timeframe, the Adaptation Strategy described in mitigation measure HY-12a.2 shall be implemented, which will may consist of installing storm drain pumps that will be funded by the project funding mechanism established during the initial development phase.

Impact of Hunters Point Shipyard Phase II

Impact HY-12b **Implementation of the Project at HPS Phase II would not place housing in a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map. (Less than Significant with Mitigation) *[Criterion M.g]***

According to proposed site plans, the portions of HPS Phase II that fall within a SFHA are proposed to be used for stadium parking. However, housing could be located in an area subject to flooding if the rate of sea level rise were to exceed the 36 inches that serves as the basis for Project grading plans and fill elevations, and no improvements were to be made along the shoreline.

Mitigation measure MM HY-12.a.1 requires Project finished grade elevations to be above the BFE accounting for future sea level rise. Mitigation measure MM HY-12a.2 requires that shoreline and public access improvements be designed to incorporate setbacks to accommodate sea level rise -related improvements. With implementation of this mitigation measure impacts pertaining to the placement of housing within a potential future mapped flood hazard area would remain at less-than-significant levels.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact HY–12 **Implementation of the Project would not place housing in a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map. (Less than Significant with Mitigation) *[Criterion M.g]***

The Project would place housing within a SFHA according to the preliminary FIRM for San Francisco and the City's Interim Floodplain Map (refer to Figure III.M-4). However, the preliminary grading plan for the Project site[642] shows that the site would be graded to be above the Base Flood Elevation with a safety factor of +3 feet to allow for future sea level rise with building finish floor elevations 6 inches above that (total of 3.5 feet above Base Flood Elevation). Implementation of mitigation measures MM HY-12a.1 and MM HY-12a.2 would require that all housing be elevated out of the floodplain by grading and fill, that the City's Interim Floodplain Maps (or the FEMA maps, if adopted prior to Project implementation) be updated to reflect finished grade elevations, and that open space setbacks be put in place to allow protection against future sea level rise. These mitigation measures would ensure impacts pertaining to the placement of housing within a mapped flood hazard area remain at a less-than-significant level.

[642] Winzler & Kelly, Infrastructure Plan, Candlestick Point High Grading with Sea Level Rise, June 23, 2009. Copies of these documents are on file for public review at the San Francisco Redevelopment Agency, One South Van Ness Avenue, Fifth Floor as part of File No. ER06.05.07, or at the Planning Department, 1650 Mission Street, Fourth Floor, San Francisco, CA, 94103 as part of File No. 2007.0946E.

Impact HY-13: Structures within a 100-Year Flood Hazard Area

Impact of Candlestick Point

Impact HY-13a **Implementation of the Project at Candlestick Point would not place structures within a 100-year flood hazard area that could impede or redirect flood flows. (Less than Significant) *[Criterion M.h]***

Development at Candlestick Point could place structures within a SFHA (Zone A) according to the City's Interim Floodplain Map and the preliminary FIRM for the San Francisco (refer to Figure III.M-4). Placement of structures in a SFHA is primarily a concern within riverine floodways[643] because structures placed in the floodway could redirect flows away from a flooded channel into developed areas. If a development were proposed in a designated floodway, it would require a hydraulic/hydrologic analysis to show that it would not increase the Base Flood Elevation. This issue is not of significant concern at the Project site because the Interim Floodplain Map and the preliminary FIRMs do not designate any areas that would contain structures as regulatory floodways. Therefore, the impacts of development at Candlestick Point on impeding or redirecting flood flows would be less than significant. No mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact HY-13b **Implementation of the Project at HPS Phase II would not place structures within a 100-year flood hazard area or impede or redirect flood flows. (Less than Significant with Mitigation) *[Criterion M.h]***

Development at HPS Phase II could place structures within a SFHA (Zone A) according to the Preliminary FIRM for the San Francisco (refer to Figure III.M-4). However, structures within Zone A that do not fall within a designated floodway would not be expected to impede or redirect flood flows.

Development at HPS Phase II would also place structures, including the marina and the shoreline improvements, within a Zone V SFHA, according to the preliminary FIRM for San Francisco.[644] Structures in Zone V could be subject to high-velocity wave forces that could cause damage to the structures or redirection of flood flows onto other parts of the site. Existing piers within Zone V would only be used as breakwaters for the marina and for wildlife habitat uses, and no buildings would be constructed. The shoreline improvements, including open space public access areas, would be initially designed and constructed to accommodate a 16-inch increase in sea level rise, with an adaptive management approach to accommodate greater sea level rise increases should they occur, as required by mitigation measure MM HY-12a.2. This conservative shoreline design for sea level rise, as well as the development setback from the shoreline required by MM HY-12a.2, would protect the site against coastal flooding hazards including high-velocity wave forces that could impede flood flows or cause flood flows to be directed to any portions of the site including open space or developed areas. Implementation of MM HY-12a.2 would reduce the impacts of placing structures in a Zone V SFHA to a less-than-significant level.

---

643 The floodway is the stream channel and portion of the adjacent floodplain that must remain open to permit passage of the base flood.

644 Although the City Administrator has requested revision of the preliminary FIRM to remove the Zone V designation at the Project site, it is conservatively assumed for the purposes of this analysis that (1) the FIRM will not be modified prior to approval, and (2) the FIRM could be adopted prior to implementation of the Project.

Impact of Yosemite Slough Bridge

Impact HY-13c **The Yosemite Slough bridge would not place structures within a 100-year flood hazard area or impede or redirect flood flows. (Less than Significant)** ***[Criterion M.h]***

The bridge across Yosemite Slough would not place structures within a SFHA that could generate high-velocity flood forces that could cause damage to the structure itself or adjacent structures. The Yosemite Slough bridge would be designed such that the superstructure would be well above the current 100-year flood hazard elevation in Zone V, to account for future sea level rise. Because the bridge would be designed to avoid potential impedance of flood flows, the impacts would be less than significant. No mitigation is required.

Combined Impact of Candlestick Point, Hunters Point Shipyard Phase II, and Yosemite Slough Bridge

Impact HY-13 **Implementation of the Project would not place structures within a 100-year flood hazard area or impede or redirect flood flows. (Less than Significant with Mitigation)** ***[Criterion M.h]***

As discussed in Impact HY-13a and Impact HY-13b, the preliminary FIRM for San Francisco indicates that development in portions of the Project site would occur in locations that are designated as Zone A. However, there are no designated floodways within this SFHA. Therefore, the impacts of impeding or redirecting flood flows in Zone A would be less than significant.

As discussed in Impact HY-13b, the Project would place structures within locations designated as Zone V on the preliminary FIRMs. Structures in Zone V could be subject to high-velocity flood forces that could cause damage to the structure itself or redirect flood flows into adjacent areas. There would be no buildings located in Zone V, and implementation of mitigation measure MM HY-12a.2 would require development setbacks and an adaptive strategy for future increases in sea level rise, which would protect the shoreline Zone V areas from the effects of high-velocity flood forces and reduce the impacts to a less-than-significant level.

As discussed in Impact HY-13c, the bridge would be designed to avoid potential impedance of flood flows, and the superstructure would be raised well above the current 100-year flood elevation. Therefore, the impacts would be less than significant.

Impact HY-14: Other Flood Risk

Impact HY-14 **Implementation of the Project would not expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam. (Less than Significant with Mitigation)** ***[Criterion M.i]***

According to ABAG,[645] the Project site is adjacent to, but not within, the dam failure inundation zones from failure of the University Mound South Basin and/or North Basin reservoirs (refer to Figure III.M-3).

[645] Association of Bay Area Governments (ABAG). *Interactive ABAG (GIS) Maps Showing Dam Failure Inundation,* Website: http://www.abag.ca.gov/bayarea/eqmaps/damfailure/damfail.html, accessed on September 8, 2008.

The Project shoreline includes various features, such as concrete debris, unprotected embankments, pile-supported wharves, seawalls, and bulkheads that serve to protect the Project from flooding. Several of these features lack structural integrity and could fail suddenly, as the result of a large storm event or an earthquake, or gradually, through continued deterioration. Failure of these features could expose people or structures to flood hazards.

Mitigation measure MM HY-14 would require implementation of improvements recommended in Moffatt and Nichol's shoreline evaluation. In accordance with these recommendations, areas along the shoreline would be developed as open space, which would allow for implementation of additional flood control improvements, if necessary, in the case of a higher-than-planned sea level rise. The shoreline improvements would also reinforce the structural integrity of the existing shoreline, reducing the risk of sudden structural failure of deteriorated shoreline features. Such improvements would provide added protection against Project site flooding.

- *MM HY-14* *Shoreline Improvements to Reduce Flood Risk. To reduce the flood impacts of failure of existing shoreline structures, the Project Applicant shall implement shoreline improvements for flood control protection, as identified in the Candlestick Point/Hunters Point Development Project Proposed Shoreline Improvements report.[646] Where feasible, elements of living shorelines shall be incorporated into the shoreline protection improvement measures.*

Therefore, the risk of harm associated with dam failure would be less than significant.

Impact HY-15: Seiche, Tsunami, and Mudflows

Impact HY-15 **Implementation of the Project would not expose people or structures to inundation by seiche, tsunami, or mudflow. (Less than Significant) *[Criterion M.j]***

Tsunamis are large sea waves generated by submarine earthquakes, or similar large-scale, short-duration phenomena, such as volcanic eruptions, that can cause considerable damage to low-lying coastal areas. A substantial tsunami wave could affect areas of Project site adjacent to the coastline. Seiches are waves, also caused by large-scale, short-duration phenomena, which result from the oscillation of confined bodies of water (such as reservoirs, lakes, and bays) that also may damage low-lying adjacent areas, although not as severely as tsunamis. Mudflow hazards typically occur where unstable hillslopes are located above gradient, where site soils are unstable and subject to liquefaction, and when substantial rainfall saturates soils causing failure.

Inundation caused by a seiche would be triggered by seismic activity, tsunamis, or tides. Tidal records for the San Francisco Bay have been maintained for over 100 years, and during that time, a damaging seiche has not occurred. A seiche of approximately 4 inches occurred during the M8.3 1906 earthquake. It is probable an earthquake similar to the 1906 event would be the largest experienced in the Bay Area;[647] consequently a seiche larger than 4 inches is considered unlikely to occur. Finished grade elevations for the Project would protect the Project site from a seiche; therefore the impacts would be less than significant.

---

646 Moffatt & Nichols, 2009, Candlestick Point / Hunters Point Redevelopment Project Proposed Shoreline Improvements, prepared for Lennar Urban, September, 2009.

647 Working Group On California Earthquake Probabilities, *Earthquake Probabilities in the San Francisco Bay Region: 2002–2031***,** United States Geological Survey Open-File Report 03-214, Appendix D. "Magnitude and Area Data for Strike Slip Earthquakes," Dr. William L. Ellsworth, Research Seismologist, USGS, 2003.

- The expected 100-year wave run-up height from a tsunami at the South Basin is -3.8 feet SFCD.[648] Even with a sea level rise of 3 feet, the 100-year wave run-up at South Basin would increase to -0.7 SFCD. The expected 100-year tsunami wave run-up at India Basin is -2.2 SFCD.[649] Accounting for sea level rise, 100-year wave run-up at India Basin would increase to +0.8 feet SFCD. Development finished grades, which account for sea level rise and 100-year flood elevations, would be over 1 foot above this potential tsunami wave run-up elevation. Therefore, the impacts from tsunami and seiche inundation would be less than significant. No mitigation is required.

Refer to the Section III.L for a discussion of the impacts related to mudflows and other types of landslides.

Cumulative Impacts

The geographic context for the analysis of hydrology and water quality cumulative impacts is often site-specific because each project site has a different set of physical considerations limiting development and construction. The following impacts identified for the Project are site-specific and would not contribute to impacts from other development projects: placement of housing in a 100-year flood hazard area, flooding in areas adjacent to the Bay, and exposure of people or structures to inundation by seiche, tsunami, mudflow, or dam failure. Some effects, however, particularly those pertaining to water quality, do have potential to contribute to impacts from other developments. Even when the pollutants and sediments generated by each individual project are minor, the additive effect of cumulative development in a watershed could have an adverse effect on the receiving waterbody. Because the extent of hydrology impacts can vary, the geographic context for each impact criterion is called out within the impact discussion.

With respect to cumulative effects on water quality associated with construction, all future development within the Islais Creek and Yosemite Basins would be required to conform to applicable WDRs, for example, the Construction General Permit, Wastewater Discharge Permit Order No. R2-2008-0007, and potentially General Permits Orders No. R2-2004-0055, R2-2006-0075, R2-2007-0033 (for certain types of construction dewatering). To obtain coverage under these permits, cumulative development projects would be required to implement construction BMPs similar to those recommended for the Project. Construction impacts on water quality would therefore be less than significant.

- Construction and operation of cumulative development would not deplete groundwater supplies or interfere with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level. The groundwater basins underlying the Project site are not used for water supply; thus, the groundwater level has remained relatively constant over time. Although multiple dewatering projects within the groundwater basin could reduce the water table temporarily, this effect would be offset by infiltration. Thus, cumulative development would have a less-than-significant impact on groundwater recharge.

Construction activities would alter the drainage pattern of the various development sites within the Islais Creek and Yosemite Basins, as at the Project site. Over time, construction has substantially changed the

[648] Garcia, A.W. and Houston, J.R., 1975. *Type 16 Flood Insurance Study: Tsunami Predictions for Monterey and San Francisco Bays and Puget Sound*, United States Army Corps of Engineers Technical Report H-75-17, Figure 58, converted to SFCD.
[649] Garcia, A.W. and Houston, J.R., 1975. *Type 16 Flood Insurance Study: Tsunami Predictions for Monterey and San Francisco Bays and Puget Sound*, United States Army Corps of Engineers Technical Report H-75-17, Figure 58., converted to SFCD.

hydrology of San Francisco, resulting in localized changes, and in some cases, adverse effects such as flooding. The cumulative alteration of the drainage patterns of the watersheds would therefore be considered significant and adverse. However, the Project's contribution to this cumulative impact would not be considerable, because overall, the Project would not substantially change the existing drainage patterns at the Project site.

Both the construction and operation of cumulative development would have the potential to exceed the capacity of existing and planned storm sewers. As foreseeable development is constructed, the demand for conveyance capacity will increase. The SFPUC's Stormwater Sewer Master Plan is under development and is expected to address the need for additional sewer system capacity for planned future development through capital improvements. Individual projects may also be required to provide on-site treatment and retention capacity. Finally, the City's Green Building Ordinance requires treatment of 0.75 inch of stormwater runoff and a 25 percent reduction in runoff from the 2-year 24-hour storm event (the latter standard applies only to discharges to the combined sewer) compared to existing conditions (based on the LEED® standards). As a result of these planning efforts and policies, the cumulative impact on the capacity of existing and planned storm sewers would be less than significant.

- Cumulative development in the watershed, including development of the Yosemite Slough Restoration Project and at Executive Park, HPS Phase I, India Basin Shoreline, Jamestown, Brisbane Baylands, and Visitacion Valley, could contribute to violations of water quality standards or WDRs. The Lower Bay, the receiving waterbody, has noted impairments for chlordane, dichlro-diphenyl-trichloroethane (DDT), dieldrin, dioxin compounds, exotic species, furan compounds, mercury, and polychlorinated biphenyls (PCBs).[650] Additional development could exacerbate existing pollutant concentrations. However, future development in the watershed would likely use the combined sewer system infrastructure, provided it is in good condition. Therefore, these projects would need to follow SFPUC requirements for combined sewer areas once these requirements are developed. In addition, foreseeable development projects would be required to implement operational BMPs to control release of pollutants, similar to the Project. Therefore, the overall effect on water quality would be less than significant.

  Structures placed within an area subject to flooding can redirect flood flows, resulting in impacts on surrounding properties. Cumulative development surrounding the Project site could contribute to such an effect by erecting buildings and other structures within an area subject to inundation. However, it is anticipated that cumulative development in the floodplain would be subject to mitigation similar to that proposed for the Project and would be required to obtain Floodplain Development Permits from the City Administrator prior to buildout. To acquire such a permit, the project applicants for individual development projects must demonstrate that the proposed buildings or structures would not redirect flood flows such that an adverse physical effect would occur. Thus, cumulative impacts for this criterion would be less than significant.

Volume IV: Final EIR Comments & Responses (Section A through Letter 49)
Volume V: Final EIR Comments & Responses (Letter 50 through Letter 86)
Volume VI: Final EIR Comments & Responses (Letter 87 through Section G)

CHAPTER IX Comments and Responses IX-1

A. Introduction ..... C&R-1
- A.1 Purpose of the Comments and Responses Document ..... C&R-1
- A.2 Environmental Review Process ..... C&R-1
- A.3 Document Organization ..... C&R-3

B. Refinements Since Publication of the Draft EIR ..... C&R-4
- B.1 Project Refinements ..... C&R-5
- B.2 Variant Refinements ..... C&R-6
- B.3 Modifications to Mitigation Measures ..... C&R-9
- B.4 Subalternative 4A: CP HPS Phase II Development Plan with Historic Preservation ..... C&R-10

C. Project Approvals ..... C&R-12

D. List of Persons Commenting ..... C&R-13

E. Comments and Responses ..... C&R-21
- E.1 Master Responses ..... C&R-21
  - Master Response 1: SB 18 ..... C&R-22
  - Master Response 2: Potential Native American Burial Sites ..... C&R-24
  - Master Response 3: Impacts of the Project on Yosemite Slough (Biological Resources) ..... C&R-28
  - Master Response 4: Purpose and Benefits of the Yosemite Slough Bridge ..... C&R-54
  - Master Response 5: Health of Bayview Hunters Point Community ..... C&R-66
  - Master Response 6: Seismic Hazards ..... C&R-77
  - Master Response 7: Liquefaction ..... C&R-82
  - Master Response 8: Sea Level Rise ..... C&R-88
  - Master Response 9: Status of the CERCLA Process ..... C&R-105
  - Master Response 10: Pile Driving through Contaminated Soils ..... C&R-113
  - Master Response 11: Parcel E-2 Landfill ..... C&R-115
  - Master Response 12: Naturally Occurring Asbestos ..... C&R-122
  - Master Response 13: Post Transfer Shipyard Cleanup ..... C&R-125
  - Master Response 14: Unrestricted Use Alternative ..... C&R-132
  - Master Response 15: Proposition P and the Precautionary Principle ..... C&R-134
  - Master Response 16: Notification Regarding Environmental Restrictions and Other Cleanup Issues ..... C&R-138
  - Master Response 17: Enforcement of Environmental Restrictions and Mitigation Measures ..... C&R-142
  - Master Response 18: Traffic Mitigation Measures ..... C&R-144
  - Master Response 19: Proposed BAAQMD Guidelines ..... C&R-154
- E.2 Individual Responses ..... C&R-166
  - Responses to Written Comments ..... C&R-166
  - Responses to Oral Comments ..... C&R-1871

F. Draft EIR Revisions ..... C&R-2175
F.1 Changes to Executive Summary ..... C&R-2176
F.2 Changes to Chapter I (Introduction) ..... C&R-2231
F.3 Changes to Chapter II (Project Description) ..... C&R-2233
F.4 Changes to Section III.A (Introduction to the Analysis) ..... C&R-2253
F.5 Changes to Section III.B (Land Use and Plans) ..... C&R-2255
F.6 Changes to Section III.C (Population, Housing, and Employment) ..... C&R-2261
F.7 Changes to Section III.D (Transportation and Circulation) ..... C&R-2263
F.8 Changes to Section III.E (Aesthetics) ..... C&R-2277
F.9 Changes to Section III.F (Shadow) ..... C&R-2285
F.10 Changes to Section III.G (Wind) ..... C&R-2286
F.11 Changes to Section III.H (Air Quality) ..... C&R-2286
F.12 Changes to Section III.I (Noise) ..... C&R-2302
F.13 Changes to Section III.J (Cultural Resources) ..... C&R-2307
F.14 Changes to Section III.K (Hazards and Hazardous Materials) ..... C&R-2313
F.15 Changes to Section III.L (Geology and Soils) ..... C&R-2320
F.16 Changes to Section III.M (Hydrology and Water Quality) ..... C&R-2321
F.17 Changes to Section III.N (Biological Resources) ..... C&R-2327
F.18 Changes to Section III.O (Public Services) ..... C&R-2341
F.19 Changes to Section III.P (Recreation) ..... C&R-2343
F.20 Changes to Section III.Q (Utilities) ..... C&R-2350
F.21 Changes to Section III.S (Greenhouse Gas Emissions) ..... C&R-2352
F.22 Changes to Section IV.A (Introduction) [in Chapter IV (Project Variants)] ..... C&R-2353
F.23 Changes to Section IV.B (Variant 1: R&D Variant [No Stadium—Additional Research & Development]) ..... C&R-2358
F.24 Changes to Section IV.C (Variant 2: Housing Variant [No Stadium—Relocation of Housing]) ..... C&R-2366
F.25 Addition of Section IV.Ca (Variant 2A: Housing/R&D Variant [No Stadium—Relocation of Housing; Additional R&D]) [New Section] ..... C&R-2370
F.26 Changes to Section IV.D (Variant 3: Candlestick Point Tower Variants) C&R-2404
F.27 Changes to Section IV.E (Variant 4: Utilities Variant) ..... C&R-2429
F.28 Changes to Section IV.F (Variant 5: San Francisco 49ers and Oakland Raiders Shared Stadium at Hunters Point Shipyard) ..... C&R-2429
F.29 Changes to Chapter V (Other CEQA Considerations) ..... C&R-2431
F.30 Changes to Chapter VI (Alternatives) ..... C&R-2431
F.31 Changes to Chapter VIII (Acronyms/Abbreviations and Glossary) ..... C&R-2468
F.32 Changes to Draft EIR Appendices ..... C&R-2481
G. References ..... C&R-2483
G.1 References for Master Response 1 ..... C&R-2483
G.2 References for Master Response 2 ..... C&R-2483
G.3 References for Master Response 3 ..... C&R-2483
G.4 References for Master Response 4 ..... C&R-2485
G.5 References for Master Response 5 ..... C&R-2485
G.6 References for Master Response 8 ..... C&R-2486
G.7 References for Master Response 11 ..... C&R-2488
G.8 References for Master Response 19 and Air Quality Text Changes ..... C&R-2489
G.9 Other References ..... C&R-2490

SECTION III.N BIOLOGICAL RESOURCES

III.N.1 Introduction

This section of the EIR discusses existing biological resources within and surrounding the Project site and examines the potential for the Project to (1) result in substantial and adverse direct, indirect, or cumulative impacts to sensitive biological resources (including plants, wildlife, aquatic species, and vegetation communities); (2) interfere substantially with the movement of native fish or wildlife species; (3) conflict with local policies or ordinances protecting biological resources; or (4) conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan. This section analyzes both Project-level and cumulative environmental impacts, as well as feasible mitigation measures that could reduce or avoid any identified significant impacts.

Due to the length and complexity of this section, an overall description of the format and structure of the Biological Resources discussion, as well as the general approach to the analysis, is provided to assist the reader in following the discussion. First, while the boundaries of the Project site include the landside areas (i.e., those areas landward of tidal waters) that are depicted on Figure II-2 (Project Site and Context) of Chapter II (Project Description) of this EIR, the Project could result in impacts to aquatic resources that are located directly adjacent to the Project site (in the San Francisco Bay) as the result of the Project's various waterside improvements, including the shoreline improvements required to stabilize and/or reinforce the shoreline, improvements required to provide a marina, and construction of the Yosemite Slough bridge (refer to Appendix N2 [Yosemite Slough Bridge Drawing]). Therefore, this discussion focuses on both on-site landside and off-site aquatic resources.

The Study Area for this biological resources analysis includes both developed and undeveloped portions of HPS Phase II and Candlestick Point, including the entire Candlestick Point State Recreation Area (CPSRA), as well as off-site open waters adjacent to the Project site that would be impacted by Project components (i.e., breakwater, pier, etc.); refer to Figure III.N-1 (Biological Resources Study Area). The

- off-site aquatic resources discussed include Yosemite Slough (except the area of construction, which is included in the on-site impact analysis), the open water area between Candlestick Point and HPS Phase II (known as South Basin), and adjacent open waters that would be impacted by Project components (i.e., breakwaters, gangways, floats, etc.). For purposes of the evaluation of sensitive species, the Study Area is defined as the Project site and a radius of up to 5 miles beyond the Project site.

The Setting discussion describes existing biological conditions, consisting of common plant and wildlife species and habitats, sensitive plant and wildlife species and habitats, and wildlife movement/habitat connectivity conditions. The discussion was prepared by first completing an extensive literature search of potential biological resources within the Study Area, followed by completing several field surveys to document the conditions that do exist or could exist, depending on the time of year. The Setting discussion describes certain biological resources that are defined by state or federal regulations; therefore, detailed descriptions of applicable regulations are provided in the Regulatory Framework section.

BIOLOGICAL RESOURCES STUDY AREA

The Impact discussion parallels the Setting discussion in presentation, first by discussing impacts to common species or resources and discussing sensitive species or resources. This section identifies both Project-specific and cumulative environmental impacts, as well as feasible mitigation measures that could reduce or avoid the identified impacts.

III.N.2 Setting

In order to assess existing conditions and potential Project-related impacts, PBS&J staff biologists conducted reconnaissance-level surveys of the Project site on August 9, 2007, May 5, 2008, and July 8, 2008. Surveys focused on identification of vegetation communities, special-status species or their potential habitat, and other biotic resources (i.e., potential wetlands or "other waters" of the US). During surveys, biologists walked transects through each habitat type while recording plant and wildlife species observed in field notes. On July 8, 2008, Navy personnel escorted a PBS&J staff biologist through HPS Phase II. The August 2007 and July 2008 surveys were in the dry season, when most annual, biennial, and perennial herbaceous plant species were dormant or had already died back, leaving only dried plant parts (i.e., leaves, stems, fruits) for identification. Lastly, a rare plant survey was conducted in May 2008. The survey was conducted by walking representative transects through the survey area while recording every plant species observed. Although the survey was conducted within the flowering window for the special-status species that could occur within the Project site, the unusually dry weather resulted in a shorter flowering period and thus, most annual, biennial, and perennial herbaceous plant species were dormant or had already died back for the growing season, leaving only dried plant parts (i.e., leaves, stems, fruits) for identification. If a plant species could not be identified in the field, diagnostic plant structures (i.e., fruits or morphology) were collected for further analysis. Some plants observed during the survey could only be identified to the Genus level.[651]

The "baseline conditions" for this analysis are based on these field surveys, other data collected or research conducted within the Study Area over the past six years (2003–2009), and federal and state agency information resources. Sources consulted include the California Department of Fish and Game's (CDFG) Natural Diversity Database (CNDDB) for the US Geological Survey's (USGS) 7.5-minute San Francisco South and Hunters Point quadrangles; the California Native Plant Society (CNPS) electronic inventory for the USGS 7.5-minute San Francisco South and Hunters Point quadrangles; the US Fish and Wildlife Service (USFWS) Endangered and Threatened Species list for the USGS 7.5-minute San Francisco South and Hunters Point quadrangles; the *Final Report Yosemite Slough Watershed Wildlife Survey*, LSA, July 2004; the *Final Draft Significant Natural Resource Areas Management Plan*, Sections 6.17 and 6.18, San Francisco Recreation And Park Department, February 2006; the *Draft Wetlands Mitigation and Monitoring Plan*, Navy Base Realignment and Closure Program, November 2006; the *Hunters Point Shipyard and Candlestick Point State Recreation Area, Natural Environment Study Report for the Bayview Transportation Improvements Project*, Jones & Stokes, June 2009; the *Final Delineation of Wetlands and Other Waters*, H.T. Harvey & Associates, Revised 13 July 2009 and October 13, 2009; the *Draft Sustainability Plan* for the Project, Arup North America Ltd, March 2009; PBS&J's *Candlestick Point/Hunters Point Shipyard Biological Technical Report* prepared for the San Francisco Redevelopment Agency (refer to Appendix N1 [Biological Resources Technical Report]), San Francisco Planning Department, December 11, 2008 updated November 2, 2009; and Project plans and graphic renderings.

[651] Plants that were identified to the Genus level are not special-status or rare plants, and, therefore, this taxonomic unit of classification does not affect the findings of this report.

- Information from these sources and from PBS&J's reconnaissance-level surveys was used to identify and characterize existing conditions at the Project site, and accordingly, were substantially relied upon for this analysis. In particular, LSA's Yosemite Slough Watershed Wildlife Survey (2004) and the Final Delineation of Wetlands and Other Waters conducted by H.T. Harvey & Associates (2009) provided specific information about the Study Area. LSA coordinated a wildlife survey of the Yosemite Slough Watershed between January 2003 and April 2004.[652] The survey of the Yosemite Slough Watershed included both the entire CPSRA and adjacent open water areas between HPS Phase II and the peninsula that forms the eastern extension of CPSRA.[653] From north to south, the Yosemite Slough Watershed Wildlife Survey Study Area is roughly bordered by Thomas Avenue, Ingalls Street, Carroll Avenue, Arelious Walkder Drive, Arelious Walker Drive, and the Hunters Point Expressway (Figure III.N-1). Although this survey covered only a portion of the Project site, it provides the most comprehensive data set available regarding the occurrence of wildlife in the area, and is thus cited heavily in the descriptions of existing conditions in this section. Also, because the majority of the Project site that was not covered by the Yosemite Slough Watershed Wildlife Survey is developed, we expect wildlife communities elsewhere on the Project site to be similar or depauperate in comparison to, those documented within the Yosemite Slough Survey's study area.

H.T. Harvey & Associates prepared a delineation of wetlands and other jurisdictional waters potentially meeting the regulatory definition of Waters of the United States within a majority of the Project site (February 2009 and revised on July 13 and October 13, 2009).[654] Surveys were conducted in 2008 on September 25 and 26; November 5 and 6; and December 4, 5, and 19; and in 2009 on January 29 and 30 and May 20. The delineation included the examination of the above-mentioned areas for wetlands using the routine determination method outlined in the US Army Corps of Engineers (USACE) Wetlands Delineation Manual. H.T. Harvey assessed topographic features, drainages, potential alterations to site hydrology, and areas of significant recent disturbance, and mapped the High Tide Line (HTL). The USACE verified the findings of the delineation with a Jurisdictional Determination dated August 31, 2009. As indicated on Figure III.N-3 (Wetlands and Other Waters) later in this section, the study area for H.T. Harvey's original wetland delineation did not included several limited areas that are now considered part of the Project site. As a result, H.T. Harvey expanded its original delineation by inspecting these additional areas in the field on October 8, 2009. H.T. Harvey & Associates has amended its wetland delineation report, and verification of jurisdictional boundaries in these additional areas by the USACE is pending.

Existing conditions are described with respect to observed plant species, vegetation communities, common aquatic habitats (i.e., mud flats, open water, and eelgrass (*Zostera marina*) beds), common wildlife (i.e., invertebrates, reptiles and amphibians, birds, and mammals), common aquatic resources (i.e., fish, shellfish, and mollusks), and sensitive species and habitats (sensitive plants, sensitive vegetation communities, sensitive wildlife [invertebrates, birds, terrestrial mammals, and marine mammals], and sensitive aquatic resources [mollusks, fish, and Essential Fish Habitat (see Sensitive Aquatic Resources)]).

Observed Plant Species

As described in Appendix N1 to this EIR, a total of 187 vascular plant species were observed within the Project site during all of the biological surveys listed in the Setting section above, 103 of which are non-native. In addition, 66 of the non-native vascular plant species are considered to be invasive plant species.[655] Invasive plants are defined as those that were "moved by humans to another region." These invasive plants have a competitive advantage because they are no longer controlled by their natural predators, and can quickly spread out of control.[656] Widely scattered trees are present and appear to either be horticultural plantings associated with landscaping or represent locally naturalized specimens. Calflora's on-line Plant Name Library was used for the scientific nomenclature for plant names in this section.[657]

Vegetation Communities

For purposes of the biological resources analysis, the Study Area is first described in terms of the vegetation communities it supports, as reflected by Table III.N-1 (Vegetation Communities within the Study Area) and further discussed below. The vegetation communities are defined according to CDFG's Vegetation Classification and Mapping Program of the Biogeographic Data Branch,[658] H.T. Harvey & Associates' wetland delineation for HPS Phase II and Candlestick Point,[659] and PBS&J's Biological Technical Report prepared for the Project.[660]

As depicted in Figure III.N-2 (Study Area Habitats), the Study Area contains four non-aquatic vegetation communities: non-native annual grassland, landscaped areas/ornamental plants, salt marsh, and seasonal freshwater wetland. In addition, approximately 568.80 acres of the Study Area is "urban." This habitat is not classified as a "vegetation community" and is thus not included in the "vegetation communities" table. Urban habitat includes developed or paved areas. The Study Area also contains three aquatic habitats: mud flats, eelgrass beds, and open waters. Table III.N-1 provides the total acreages of each vegetation community within the Study Area. A description of each of the vegetation communities follows this table.

In some cases, vegetation communities may also be considered sensitive vegetation communities. In those cases, and there are three such cases in this analysis, they are also discussed under Sensitive Vegetation Communities, which follows this discussion. The three sensitive communities within the Study Area include salt marsh, eelgrass beds, and seasonal freshwater wetland habitats (also discussed under Sensitive Vegetation Communities).

b. H.T. Harvey & Associates, *Hunters Point Shipyard and Candlestick Point State Recreation Area Final Delineation of Wetlands and Other Waters, San Francisco, California*, February 2009 and revised July 13 and October 13, 2009.

Acreage discrepancies between the data contained herein and the total approximate acreage of the Study Area are due to the conversion of data from non-GIS to GIS data.

This table does not include the acreage for developed/urban areas (568.80 acres) because this classification is not a recognized vegetation community for purposes of this EIR.

* The open waters located outside of the Project boundary include those adjacent to Candlestick Point, Hunters Point Shipyard, and Yosemite Slough.

Non-native Annual Grassland

Patches of non-native annual grassland habitat are found throughout the Project site and comprise 74.72 acres. Invasive, non-native grasses characterize this community, particularly at HPS Phase II due to the intensive disturbance associated with the Navy's ongoing remediation efforts. The vegetation within this grassland consists of a mixture of invasive annuals such as wild oat (*Avena fatua*), rip-gut brome (*Bromus diandrus*), soft chess (*B. hordeaceus*), rat-tail fescue (*Vulpia myuros*), and hare barley (*Hordeum murinum var. leporinum*). Broad-leaf species occurring within the grasslands consist of wild radish (*Raphanus sativus*), painted charlock (*R. raphanistrum*), black mustard (*Brassica nigra*), Mediterranean linseed (*Bellardia trixago*), cut-leaf plantain (*Plantago coronopus*), spring vetch (*Vicia sativa*), red valerian (*Centranthus ruber*), and Italian thistle (*Carduus pycnocephalus*). Additionally, garland chrysanthemum (*Chrysanthemum coronarium*) has naturalized across much of the grasslands and showy stands of these flowers are present throughout the entire CPSRA.

Small distinct colonies of native perennial bunch grasses grow in a few areas at HPS Phase II. Clusters of single species or a combination of species including purple needle grass (*Nassella pulchra*), blue wild rye (*Elymus glaucus*), and red fescue (*Festuca rubra*) grow sporadically throughout the Project site. These small isolated occurrences of native grasses are not large enough to warrant identification as a separate vegetation community.

Portions of the Study Area, including uplands along Yosemite Slough, include ruderal vegetation such as fennel (*Foeniculum vulgare*) intermixed with non-native grasses such as wild oats and Italian rye (*Lolium multiflorum*). Shrubs, mainly coyote brush (*Baccharis pilularis*), are scattered throughout the upland surrounding Yosemite Slough area.

FIGURE III.N-2

Candlestick Point — Hunters Point Shipyard Phase II EIR

STUDY AREA HABITATS

Landscaped Areas/Ornamental Plants

Landscaped areas make up about 44.67 acres of Candlestick Point and include areas landscaped with native and non-native ornamental shrubs and trees, particularly near the walking paths along the shoreline of Candlestick Point. A tree survey[661] (provided in Appendix N4) was conducted for the Project within all of the Project site except the portion of CPSRA that is not subject to the land transfer and is not expected to be substantially modified. This survey identified trees primarily in areas mapped as "Landscaped/Ornamental", "Urban", and "Non-Native Annual Grassland" on Figure III.N-2. For the purpose of this survey, a "tree" was defined as any stem of a woody plant with a tree-like (as opposed to shrubby) growth habit measuring at least 2 inches in diameter at a height of 4.5 feet above the ground. As a result, single trees with multiple stems measuring at least 2 inches in diameter were represented as multiple "trees," and the high number of trees recorded during this survey was driven largely by such multi-stemmed individuals. The tree survey recorded approximately 1,976 tree stems at least 2 inches in diameter on 1,068 individual plants on Candlestick Point and 854 tree stems at least 2 inches in diameter on 328 individual plants on HPS Phase II.

On Candlestick Point, the vast majority of these trees consisted of multi-stemmed lollypop trees (*Myoporum laetum*); eucalyptus (*Eucalyptus* spp.), pines (*Pinus* spp.), and olives (*Olea europeaea*) were also well represented on Candlestick Point. All four of these species are non-natives. The most common native trees on Candlestick Point are California live oak (*Quercus agrifolia*), flannel bush (*Fremontodendron californicum*), and California buckeye (*Aesculus californica*). Monterey pine (*Pinus radiata*) and ornamental cypress (*Cupressus* spp.) are also common, although neither is native to San Francisco. There are several specimens of the native California bay (*Umbellularia californica*) and blue elderberry (*Sambucus nigra* ssp. *caerulea*) as well. Non-native, ornamental lollypop trees (*Myoporum laetum*) grow along the northwestern edge of Candlestick Point, and Australian tea trees (*Leptospermum laevigatum*) are scattered along the trails of the CPSRA. Native shrubs include coyote bush, ornamental buckbrush (*Ceanothus* spp.), firethorn (*Pyracantha* spp.), coffeeberry (*Rhamnus californica*), hummingbird sage (*Salvia spathacea*), and black sage (*S. mellifera*) which grow along the paths in clusters that are a combination of planted and volunteer specimens. Non-native evergreen shrubs such as rockrose (*Cistus* spp.) are common throughout the Project site and in some locations have naturalized.[662]

On HPS Phase II, trees recorded during the tree survey were dominated by small, multi-stemmed toyon (*Heteromeles arbutifolia*; a native species, though the trees on HPS appear to be of an ornamental variety) and several non-natives, including London planetree (*Platanus* x *acerifolia*) and acacia (*Acacia* spp.).

Salt Marsh

Salt marsh habitat forms along the margins of estuaries and bays whose shorelines are shallow and protected. In the Study Area, it totals approximately 4.50 acres on site and 0.05 acre in areas of off-site (i.e., areas of Yosemite Slough outside of the Project boundary) Project work.[663] It occurs in limited areas along the shoreline where riprap does not extend to the waterline and prohibit the growth of vegetation, and in several nontidal areas in the southwestern portion of HPS. Narrow patches of salt marsh habitat, varying

[661] H.T. Harvey & Associates, *Candlestick Point/Hunters Point Shipyard Tree Survey*. October 16, 2009.
[662] Naturalized plants are those that were originally installed as ornamental plantings but are now found growing 'naturally' in a variety of habitats.
[663] H.T. Harvey & Associates, *Hunters Point Shipyard and Candlestick Point State Recreation Area Final Delineation of Wetlands and Other Waters,* San Francisco, California, February 2009 and revised July 13, 2009 and October 13, 2009.

in length from 20 to 100 feet, occur sporadically along the shoreline of the Project site, and throughout Yosemite Slough.[664]

Salt marshes are often subject to tidal influences, and species composition of tidal salt marsh vegetation varies along gradients based on elevation. The amount of time an area is inundated determines the primary species of plants found there. The highest elevations typically support almost pure stands of pickleweed (*Salicornia virginica*), which also dominates the patches of nontidal salt marsh on HPS. Associated species that occur in the zone around the high tide elevation include salt grass (*Distichlis spicata*), European sea rocket (*Cakile maritima*), coastal gumweed (*Grindelia stricta*), and sea lavender (*Limonium californicum*). Slightly lower areas above the Mean High Water (MHW) elevation support cord grass (*Spartina* spp.). In the area above the HTL, common iceplant (*Carpobrotus edulis*) grows in some locations, carpeting the upland margins in a dense monoculture. The low growing shrub silver beach bur (*Ambrosia chamissonis*) also grows in the upland areas along the shoreline.

Seasonal Freshwater Wetland

Seasonal freshwater wetland habitat occupies 0.20 acre in two linear features at the southern and west-central margins of HPS Phase II. These wetlands are characterized by the presence of annual wetland grasses and forbs in depressions that hold water for a short to medium duration during the rainy season. One of these wetlands, in the southwestern portion of HPS Phase II, consists of pools that are shallow basins that lack drainage outlets. Seasonal water inundation in these pools creates a condition favoring hydrophytic (water-loving) plants such as spearscale (*Atriplex triangularis*), salt grass, bird's-foot trefoil (*Lotus corniculatus*), prickly ox-tongue (*Picris echioides*), saltmarsh bulrush (*Bolboschoenus robustus*), Italian ryegrass (*Lolium multiflorum*), rabbit's foot grass (*Polypogon monspeliensis*), and willow dock (*Rumex salicifolius*), as observed in HPS Phase II.[665] The second seasonal freshwater wetland, in the west-central part of HPS Phase II, consists of a narrow swale/ditch that is apparently fed by groundwater seepage.

Common Aquatic Habitats

Mud Flats

Mud flats are the broad expanses of the San Francisco Bay bottom that are exposed during low tides. These areas are comprised of very soft sediments and do not support any vegetation other than eelgrass beds, which may occur within mud flats. Mud flats are an important habitat because they support a vast array of crustaceans, worms, and other invertebrates that are important food sources for resident and migratory shorebirds and waterfowl. Mud flats are exposed at low tides once or twice a day along the shore south of CPSRA and along the shorelines of Yosemite Slough and South Basin. These mud flats are relatively limited in extent compared to the vast mud flats present in other parts of San Francisco Bay, and as a result, numbers of shorebirds using these mud flats are low except for occasional, brief migratory pulses of birds.

[665] PBS&J, *Candlestick Point/Hunters Point Shipyard Project Biological Technical Report*, Prepared for San Francisco Redevelopment Agency and San Francisco Planning Department, 2009, which is provided as Appendix N1 to this EIR.

Open Water (San Francisco Bay)

San Francisco Bay (also referred to as "the Bay" in this section) is the largest estuary on the California Coast, covering between 400 and 1,600 square miles depending on which bays are included.[666] Fresh water enters primarily through the Sacramento-San Joaquin Delta and mixes with seawater that enters via the Golden Gate. Tidal action and freshwater runoff determine the salinity of the Bay. For the purpose of this assessment, the term "open water" refers to unvegetated tidal areas located below the MHW elevation, which in this area is approximately 5.87 feet relative to the North American Vertical Datum of 1988 (NAVD88)[667] or 11.80 relative to the San Francisco City Datum (SFCD).[668] This is the same area regulated by the USACE under Section 10 of the *Rivers and Harbors Act*. These areas are subject to the normal ebb and flood of the tide. For example, mud flat habitats described above are a subset of open water aquatic habitats since these areas are inundated for at least half the tidal cycle; for this reason, acreages of mud flat and open water habitats are not distinguished in Table III.N-1. Open water habitats support an array of relatively common estuarine/marine species from encrusting tunicates, sponges, and algae to bottom-dwelling fish such as the Pacific halibut (*Hippoglossus stenolepis*), flounder, and sole, to more open water fish such as the Pacific herring (*Clupea pallasi*), Pacific sardine (*Sardinops sagax*), and anchovies (*Anchoa* spp.). The on-site open waters are those nearshore areas below the MHW elevation where Project work could occur (i.e., sea wall enhancements and marina improvements). Off-site open waters within a 5-mile radius of the Project site were also considered for their potential to support sensitive species (as described under "Sensitive Species and Habitats" below). These areas are considered here because most of the sensitive species potentially occurring there have the ability to move to and from the Study Area at any time.

Eelgrass Beds

Eelgrass is an aquatic plant found on soft mud-bottom bays and estuaries along the Pacific coast. It occurs in both subtidal and intertidal areas of San Francisco Bay and approximately 1.99 acres of it occur within the Study Area.[669] Eelgrass beds are considered a sensitive resource and, therefore, are discussed in detail under Sensitive Species and Habitats.[670]

667 H.T. Harvey & Associates, *Hunters Point Shipyard and Candlestick Point State Recreation Area Final Delineation of Wetlands and Other Waters,* San Francisco, California, February 2009 and revised July 13, 2009 and October 13, 2009.

668 San Francisco City Datum (SFCD) is a local vertical geodetic reference system specific to the City and County of San Francisco and formally established in 1964 as 8.616 feet above the National Geodetic Vertical Datum of 1929 (NGVD29), making it about 8.13 feet above mean sea level. The North American Vertical Datum was established in 1988 (NAVD88) and generally has replaced NGVD29 as a standard reference. Elevations expressed in NGVD29 may be converted to NAVD88 by adding 2.69 feet.

Common Wildlife

Invertebrates

Fourteen butterfly species were observed during the Yosemite Slough Watershed Wildlife Survey.[671] Common butterflies observed during that survey included cabbage whites (*Pieris rapae*), anise swallowtails (*Papilio zelicaon*), and common checkered skippers (*Pyrgus communis*). Other butterflies observed include mustard white (*Pieris napi*), orange sulphur (*Colias eurytheme*), California hairstreak (*Satyrium californicum*), gray hairstreak (*Strymon melinus*), western pygmy-blue (*Brephidium exile*), spring azure (*Celastrina ladon*), west coast lady (*Vanessa annabella*), red admiral (*Vanessa atalanta*), common buckeye (*Junonia coenia*), and common ringlet (*Coenonympha tullia*), and monarch butterfly (*Danaus plexippus*). Numerous other invertebrate species, including insects, crustaceans, worms, and other taxa, occur on the site as well.

Reptiles and Amphibians

The Yosemite Slough Watershed Wildlife Survey recorded three snake species, two lizard species, and one amphibian.[672] Reptiles and amphibians observed included California slender salamander (*Batrachoseps attenuatus*), southern alligator lizard (*Elgaria multicarinata*), western fence lizard (*Sceloporus occidentalis*), gopher snake (*Pituophis melanoleucus*), ring-necked snake (*Diadophis punctatus*), and western garter snake (*Thamnophis elegans*). The western fence lizard, California slender salamander, and southern alligator lizard were found in relatively high numbers, with survey maxima (i.e., the maximum number of individuals observed on a single survey) of 49, 43, and 21 individuals, respectively. However, the other species were represented by few individuals, suggesting that populations of these other species are sparse in the area.

Amphibians had the lowest diversity within the Yosemite Slough Watershed Survey area, with only one species observed (the California slender salamander).[673] The California slender salamander frequents grassland, chaparral, woodland, forest, and yards and vacant lots in some suburban areas. It takes refuge under logs, boards, bark, and in damp leaf litter and rotting logs. It lays its eggs in late fall and winter, often in communal nests.[674] The San Francisco Bay and the small seasonal wetlands on the site do not provide suitable aquatic habitat for amphibians, primarily due to high salinity. The few freshwater habitats on or near the Project site do not provide breeding habitat for amphibians such as frogs or toads, likely because of their very shallow and/or ephemeral nature.[675]

Reptiles also appeared to have relatively low diversity, with only five species observed. The abandoned fields, extensive debris (providing cover), and presence of prey (i.e., mice, invertebrates, salamanders) provide suitable habitat for these five species.[676] The upland areas, dominated by disturbed vegetation and non-native grassland, support the snake and lizard species.[677]

During one survey, 21 southern alligator lizards were observed in silvery beachweed along the shoreline of the South Basin (refer to Map 2 of the Yosemite Slough Watershed Wildlife Survey for a graphic representation of the location of the South Basin).[678] The lizards were all juveniles and may have been from a single clutch that had been laid in the silvery beachweed.[679]

Although the Yosemite Slough Watershed Wildlife Survey covered only Candlestick Point and the southern shoreline of HPS Phase II, it is expected that a lower abundance of these common reptile and amphibian species would be found within the disturbed areas within HPS Phase II than at Candlestick Point. Recent, intensive disturbance due to ongoing remediation activities has undoubtedly reduced populations of these species on HPS Phase II. A few individuals of these reptiles and amphibians may occur within the developed portions of the Project site, which represents approximately 80 percent of the overall acreage of the site, but numbers are expected to be very low in such low-quality habitat.

Birds

One hundred and eighteen bird species (which are named herein according to the American Ornithologists' Union Checklist of North American Birds[680] except for sensitive subspecies recognized by CDFG or USFWS) were observed during the Yosemite Slough Watershed Wildlife Survey.[681] Of these, 51 species were represented by a maximum count of five or fewer individuals, indicating that, for many bird species, the site is used by relatively low numbers of individuals.[682] The majority of the species observed were terrestrial species, followed by shorebirds, waterfowl, gulls and terns, and raptors (in descending order). Terrestrial habitats supported large numbers of some common bird species such as white-crowned sparrows (*Zonotrichia leucophrys*), western meadowlarks (*Sturnella neglecta*), and house finches (*Carpodacus mexicanus*). The landbirds that are most abundant on the site are those associated with the weedy, ruderal habitats dominating the Project site and those tolerant of the urbanization and associated disturbance resulting from the site's location. In contrast, very few Neotropical and other long-distance migrant songbirds were recorded during this study. Studies have documented that bird species diversity is closely associated with structural habitat complexity. Bird species diversity (a measure of the number of species in a given area) increases with increasing foliage height diversity (a measure of the number and diversity of vertical layers of vegetation in that area).[683,684] While this has been best studied in breeding birds, the structural complexity of habitat also influences the degree to which an area provides resources to migrant birds. Multi-layered vegetation, with well-developed ground, understory, and canopy layers, would support greater diversity of migrants than the structurally simple vegetation that dominates most of Candlestick Point and HPS Phase II. Also, breeding bird abundance is often closely associated with the density or volume of vegetation, with increasingly dense vegetation supporting more individual birds[685]. The sparse

vegetation present on most of the Project site limits the value of the site to breeding and migratory birds. Numbers and diversity of landbirds on HPS Phase II are likely lower than on Candlestick Point owing to the recent, intensive disturbance and even lower abundance of trees and shrubs on HPS Phase II.

The waters of the South Basin and the Bay surrounding the Study Area are used by a variety of waterbirds, some of which are fairly abundant. Common waterbirds observed in these waters include double-crested cormorant (*Phalacrocorax auritus*), California gull (*Larus californicus*), greater scaup (*Aythya affinis*), ruddy duck (*Oxyura jamaicensis*), surf scoter (*Melanitta perspicillata*), and bufflehead (*Bucephala albeola*). While these birds forage primarily or solely in aquatic habitats, some species, such as cormorants, California brown pelicans (*Pelecanus occidentalis californicus*), gulls, and possibly terns roost in large numbers on piers on HPS Phase II. Small numbers (fewer than 10 pairs) of western gulls (*Larus occidentalis*) nest on two rocks in South Basin known as Double Rock. Shorebirds such as the western sandpiper (*Calidris mauri*), least sandpiper (*Calidris minutilla*), and dunlin (*Calidris alpina*) forage on intertidal mud flats and along the shoreline of Candlestick Point and the southern part of HPS Phase II, typically in low numbers but occasionally in higher numbers when migratory pulses of shorebirds are present in the Bay. The majority of the Study Area is developed or urbanized and supports relatively few species of birds.

In addition to the 118 bird species recorded during the Yosemite Slough Watershed Wildlife Survey, that survey's report listed an additional 36 species that had been recorded by a local birder, Mr. Alan Hopkins, over the past 20 years.[686]

Mammals

The most abundant mammal observed during the Yosemite Slough Watershed Wildlife Survey was the California ground squirrel (*Spermophilus beecheyi*). This species was observed along the shoreline and riprap areas of HPS Phase II and Candlestick Point, as well as in grassland and ruderal habitats and under trees and shrubs on Candlestick Point. The substrate along the shoreline is composed mostly of small rubble such as broken bricks that had been used as fill. Riprap composed of large rocks was placed along exposed sections of the shoreline, providing refugia for small mammals.[687] Other mammals observed during the survey included feral domestic cat (*Felis silvestris*), feral domestic dog (*Canis familiaris*), raccoon (*Procyon lotor*), striped skunk (*Mephitis mephitis*), harbor seal (*Phoca vitulina*), black-tailed jackrabbit (*Lepus californicus*), Botta's pocket gopher (*Thomomys bottae*), California vole (*Microtus californicus*), and Norway rat (*Rattus norvegicus*). Of the 10 species recorded by the LSA study, three are non-natives (domestic dog, domestic cat, and Norway rat); two are common urban-adapted species (raccoon and striped skunk); and one occurs infrequently in aquatic areas (harbor seal). Of the remaining four species, the Botta's pocket gopher and California vole were represented by no more than one individual on a given survey and thus may be uncommon on the site. As mentioned for reptiles and amphibians above, mammal diversity and abundance on HPS Phase II are expected to be lower than on Candlestick Point, as recent, intensive disturbance by remediation activities has likely reduced mammal populations there. The shorelines, vacant lots, and undeveloped ruderal/non-native grassland areas of HPS Phase II and CPSRA are surrounded by urban and industrial

[686] Golden Gate Audubon Society, *Final Report Yosemite Slough Watershed Wildlife Survey 2003–2004*, prepared by LSA, July 27, 2004.
[687] Ibid.

development, which limits the potential for dispersal of mammals in and out of the site. There are no CNDDB reports of the occurrence of any special-status mammal species in the Study Area.

Common Aquatic Resources

Fish, Crabs, and Mollusks

San Francisco Bay supports a diverse assemblage of fish species. These vary from resident fish such as assorted flat fish (flounder and sole) to a variety of rockfish (*Sebastes* spp.) and to migratory species such as Pacific herring, Pacific sardines, anchovies, and salmonids (*Oncorhynchus* spp.) which spend varying portions of their life cycle in the Bay. Estuaries provide important spawning habitat for fish and the San Francisco Bay is no exception. Pacific herring spawn in the Bay and support a small commercial fishery. Other fish for which adults spawn in the Bay include flounder, sole, and Pacific halibut. Juvenile sturgeon (*Acipenser* spp.) rear in the Bay for an undetermined length of time before moving to the ocean.

Shellfish found in the Bay and within the vicinity of the Study Area include Dungeness crab (*Cancer magister*), other rock crab, and shrimp. Dungeness are the target of an important commercial fishery in the open ocean and the Bay is important rearing habitat for young crab. Crab hatch in the Gulf of the Farallones and after several larval stages, migrate into the Bay and rear primarily in San Pablo and Suisun bays,[688] over 20 miles north of the Study Area.

The Bay also supports a variety of mollusks. These include native clams, mussels, oysters, and snails (gastropods). Some of these are native (i.e., bent-nosed macoma [*Macoma nasuta*], Olympia oyster [*Ostrea conchaphila*], and limpets [*Acmaea* spp.]) while others have been introduced either intentionally such as the Atlantic oyster (*Crassostrea virginica*) or unintentionally such as overbite clam (a.k.a. Asian clam; *Corbula amurensis*). Many of the clams use soft-bottom sediments and could be found on the seafloor near the Project site. Most oysters require a solid substrate for attachment. Suitable habitat for oysters and mussels is found throughout the Study Area on bulkheads, pilings, and riprap associated with the shoreline.

In addition to the native fish and shellfish, the Bay supports a vast array of introduced species. Most of these have been introduced in ballast water of trans-Pacific traveling cargo ships. Species suspected of being ballast water introductions include Chinese mitten crab (*Eriocheir sinensis*), yellowfin goby (*Acanthogobius flavimanus*), and overbite clam. Other species, including striped bass (*Morone saxatilis*) and American shad (*Alosa sapidissima*), have been introduced to support sport fisheries. The complex interaction between introduced and native species within the Bay continues to be the topic of much debate and study.

The open water of the Study Area is part of or directly connected to the Bay and all of the Bay fish species can move freely into and out of the Study Area at any time. Because of this, the species assemblage within and adjacent to the Project site is expected to be representative of the central Bay as a whole.

The portion of the San Francisco Bay immediately adjacent to the Project site has been highly modified over the years to support commercial shipping, industrial uses, and US Naval activities, and virtually the entire shoreline of the Study Area is composed of fill of various kinds. As a result, the shorelines are almost

[688] California Department of Fish and Game (CDFG), 2009. Dungeness crabs (*Cancer magister*). Website: http://www.delta.dfg.ca.gov/baydelta/monitoring/cmag.asp. Accessed July 16, 2009.

exclusively comprised of bulkheads and riprap. Dredging of shipping channels has occurred within the nearshore areas. All of these actions have combined to reduce the aquatic habitat complexity. Reductions in habitat complexity reduce the number of species that routinely utilize a particular area,[689] and, therefore, the numbers of resident fish species within the Study Area are expected to be similar to other developed areas of the Bay.

Marine Mammals

The most common marine mammals within San Francisco Bay are harbor seals (*Phoca vitulina*) and California sea lions (*Zalophus californianus*), both of which are protected under the *Marine Mammal Protection Act*. The *Marine Mammal Protection Act* does not bestow a particular status designation for the species it protects, which is similar to the *Migratory Bird Treaty Act*. Instead, the *Marine Mammal Protection Act* and the *Migratory Bird Treaty Act* equally protect all marine mammals and native birds, respectively.

Harbor Seal (*Phoca vitulina*)

Harbor seals are year-round residents found throughout the Bay. They use haulouts scattered through the Bay to bask, rest, and use as pupping sites. The most frequently used pupping sites are in the North (Castro Rocks) and South bays (Mowry Slough); both sites are over 15 miles from the Study Area. Pupping season begins in late March and peaks in early May.[690] The closest haulout site is on Yerba Buena Island, about 6 miles from the Project site.[691] There are no known haulout locations within the Study Area. During the 2003–2004 Yosemite Slough Watershed Wildlife Survey, LSA observed nine harbor seals in the outer South Basin (open water between Candlestick Point and HPS Phase II); however, no haulouts were detected during the survey.[692] No harbor seals or haulouts were observed during surveys by PBS&J biologists for this Project.

California Sea Lion (*Zalophus californianus*)

California sea lions do not breed in the Bay, preferring offshore islands such as the Channel Islands near Santa Barbara or the Farallon Islands, but sea lions forage and rest at various locations around the San Francisco Peninsula.[693] They are relatively social animals, frequently seen basking or foraging in large groups. On May 2, 2003, a total of ten sea lions were observed hauled out on a flat, floating structure in the outer South Basin.[694] Sea lions may occur in the Study Area, but the site does not support any known haulout locations.

Sensitive Species and Habitats

The potential for special-status plant and wildlife species to occur within the Study Area was determined by assessing habitat suitability information collected during biological reconnaissance surveys conducted in August 2007 and July 2008, a rare plant survey conducted in May 2008, and a review of the CNDDB, CNPS Inventories, and USFWS databases, as previously described. In addition, approximately 29 wildlife surveys were conducted in the vicinity of Yosemite Slough between January 2003 and April 2004 (in association with the Yosemite Slough Watershed Wildlife Survey), and that survey's report included a list of additional bird species that had been observed by Mr. Alan Hopkins over the past 20 years.[695] The list of potentially occurring special-status species provided in Table III.N-5 (Special-Status Species Potentially Occurring within the Study Area) is informed by all of these sources, as well as a search of known sensitive species occurrences within a 5-mile radius of the Project site, as shown in Figure 3 (Special-Status Species Occurrences within 5-Mile Radius) in Appendix N1 to this EIR. *(Note: Table III.N-5 is provided at the end of this section due to its length.)*

Special-status species are defined as follows:

- Species listed, proposed, or candidate for listing as Threatened or Endangered by the USFWS pursuant to the federal *Endangered Species Act of 1973* (FESA), as amended
- Species designated by the USFWS as Species of Conservation Concern
- Species designated by the National Marine Fisheries Service (NMFS) as Species of Special Concern
- Species listed as Rare, Threatened, or Endangered by the CDFG pursuant to the *California Endangered Species Act of 1984* (CESA), as amended
- Species designated as Fully Protected under Sections 3511 (birds), 4700 (mammals), and 5050 (reptiles and amphibians) of the *California Fish and Game Code*
- Species designated by the CDFG as California Species of Special Concern
- Plant species listed as Category 1B and 2 by the CNPS; CNPS Category 3 and 4 species were not considered special-status species for the sake of this assessment, as they are not considered sufficiently rare on a regional level to warrant such status, though no such plants were recorded in the Study Area.
- Species not currently protected by statute or regulation, but considered rare, threatened or endangered under Section 15380 of the CEQA Guidelines (such as the Olympia oyster and Pacific herring)

Table III.N-5 identifies the special-status plant and wildlife species that have been recorded or could occur within five miles of the Study Area, along with a description of their habitat requirements, protection status, and a brief description of each species' likelihood to be present within the Study Area. Several species known to occur within five miles of the Study Area and listed in Table III.N-5 were determined not likely to occur or to be absent from the Study Area because (1) the site lacks suitable habitat or is outside of the species' range and, (2) no instances of such species were observed during any of the field surveys (these species are further discussed in the *Bayview Waterfront Project Biological Technical Report*, which is provided as

[695] Golden Gate Audubon Society, *Final Report Yosemite Slough Watershed Wildlife Survey 2003–2004*, prepared by LSA, July 27 2004.

Appendix N1 to this EIR[696]). Consequently, the detailed species' discussions and impact analysis in this EIR section address only those species in Table III.N-5 that have a "Low" or better probability to occur within the Study Area. Those species or habitats with a "Not Likely" or "Absent" likelihood of occurrence in Table III.N-5 are not addressed further because they are not expected to occur on the Study Area or be affected by Project implementation.

Sensitive Plants

The USFWS, CNDDB, and CNPS reported 41 special-status plant species as potentially occurring within the US Geological Survey's 7.5-minute San Francisco South and Hunters Point quadrangles (refer to Table 2 [Special-Status Species Potentially Occurring within the Vicinity of the Bayview Waterfront Project] in Appendix N1 to this EIR).

The Study Area is largely developed and most vegetation in the area was introduced as landscape plants and turf grass. Much of the Study Area, including virtually all of CPSRA, is located on Bay fill. Ruderal (disturbed) habitats and ornamental landscaping predominate in those portions that are not landscaped. Jones & Stokes conducted botanical habitat assessments of the Candlestick Point and HPS on October 29, 2004; March 1, 2006; October 6, 2006; and May 17, 2007.[697] PBS&J botanists conducted rare plant surveys for the Candlestick Point area in May 2008. The general absence of suitable habitat over a majority of the Study Area in conjunction with the absence of observed special-status plants, either as observed during focused surveys or cited in CNDDB species accounts, supports the conclusion that no sensitive plant species occur within the Study Area.

Sensitive Vegetation Communities and Habitats

Waters of the United States and Navigable Waters

The Study Area contains several categories of jurisdictional waters of the United States, including jurisdictional wetlands that are subject to Section 404 of the *Clean Water Act* (Section 404). The types of wetlands include salt marsh and seasonal freshwater wetlands. In addition, the Study Area also contains open waters of the San Francisco Bay, which are subject to both Section 404 of the *Clean Water Act* and Section 10 of the *Rivers and Harbors Act of 1899* (Section 10). Section 404 regulates the placement of fill into any "waters of the United States." Waters of the United States are broadly defined to include navigable waterways, their tributaries, lakes, ponds, and wetlands, including tidal waters and wetlands from the HTL seaward. Section 10 regulates the placement of fill into navigable waters of the United States, including tidal waters from the MHW elevation seaward. Section 10 waters are a subset of Section 404 waters, and are therefore not described separately for purposes of this EIR. A more detailed discussion of the requirements of Section 404 and Section 10 is provided in Section III.N.3 (Regulatory Framework).

A wetland delineation was conducted by H.T. Harvey & Associates for the Study Area that distinguished jurisdictional wetlands and other waters of the United States subject to Section 404.[698] The revised H.T.

---

[696] PBS&J, *Candlestick Point/Hunters Point Shipyard Project Biological Technical Report,* prepared for the San Francisco Redevelopment Agency, San Francisco Planning Department, December 11, 2008 updated November 2, 2009.
[697] Jones and Stokes, *Natural Environmental Study Report for the Bayview Transportation Improvements Project*, June 2009.
[698] H.T. Harvey & Associates, *Hunters Point Shipyard and Candlestick Point State Recreation Area Final Delineation of Wetlands and Other Waters,* San Francisco, California, February 2009 and revised July 13, 2009 and October 13, 2009.

Harvey & Associates wetland delineation was submitted to the USACE in July 2009 and was verified in August 2009. The study area for that delineation included the Project site and the off-site areas where Project activities would occur (Figure III.N-3 [Wetlands and Other Waters]). As indicated on Figure III.N-3, the study area for H.T. Harvey's original wetland delineation did not included several limited areas that are now considered part of the Project site. As a result, H.T. Harvey expanded its original delineation by inspecting these additional areas in the field on October 8, 2009. H.T. Harvey & Associates has amended its wetland delineation report, and verification of jurisdictional boundaries in these additional areas by the USACE is pending.

According to USACE regulations and guidance, other waters may include lakes, seasonal ponds, channels, tributary waters, non-wetland linear drainages, and seasonal springs. Such areas are identified by the (seasonal or perennial) presence of standing or running water and generally lack hydrophytic vegetation.

In tidal waters, Section 404 other waters extend to the landward extent of vegetation associated with salt or brackish water or the HTL. The HTL is defined as the line of intersection of the land with the water's surface at the maximum height reached by a rising tide. The HTL may be determined, in the absence of actual data, by a line of oil or scum along shore objects, a more or less continuous deposit of fine shell or debris on the foreshore or berm, other physical markings or characteristics, vegetation lines, tidal gauges, or other suitable means that delineate the general height reached by a rising tide. The line encompasses spring high tides and other tides that occur with periodic frequency but does not include storm surges in which there is a departure from the normal or predicted reach of the tide due to the piling up of water against a coast by strong winds such as those accompanying a hurricane or other intense storm. Confirmation of this definition and approach used by the San Francisco District of the USACE in determining the MHW and HTL locations was obtained from the Regulatory Branch of the USACE on January 29, 2009.[699] The HTL represents the upper limit of Section 404 other waters and is approximately 1.5 to 2 vertical feet above the MHW mark.[700]

Table III.N-2 (Wetlands and Other Waters of the United States [Section 404] within the Study Area) presents the acreage of waters of the United States (including jurisdictional wetlands) that were delineated for the Study Area. The acreages of jurisdictional wetlands and waters identified in Table III.N-2 include the HT Harvey study area boundary as identified in Figure III.N-3 (which includes open waters adjacent to Candlestick Point and HPS Phase II), as well as off-site areas of Yosemite Slough that are located outside of this boundary.

b. On-site areas within Yosemite Slough refer to areas within the Study Area. Off-site areas within Yosemite Slough are those areas adjacent to the slough that are outside of the Study Area boundary.

Eelgrass Beds

Eelgrass occurs in both subtidal and intertidal areas of San Francisco Bay. The distribution of eelgrass has been mapped relatively recently (in 2003) and the results of this effort indicate that low-density eelgrass beds are found on the north side of Hunters Point peninsula offshore from the end of Earl Street and in a small patch in the South Basin.[701] Eelgrass beds form areas of important habitat for birds, fish, and crustaceans and are one of the preferred spawning habitats of Pacific herring.[702] These plants also support grazing crustaceans, shrimp, and amphipods. Because it requires light for photosynthesis, eelgrass is limited by water clarity to depths of about 6 feet or less. Because little accurate information exists about the historic distribution of eelgrass beds, and because of their current relative scarcity and importance in the overall ecology of the Bay, both the USACE and CDFG consider eelgrass beds a sensitive resource.

Sensitive Wildlife

Invertebrates

*Monarch Butterfly (*Danaus plexippus*)*

Monarch butterflies are common and widespread in California, including the San Francisco Bay area. However, because they tend to gather in winter roosting sites along the California coast in relatively few locations, roost sites that are used traditionally by large numbers of individuals are considered sensitive biological resources and, thus, this common butterfly is discussed here as a sensitive species. Wintering sites in California are associated with wind-protected groves of large trees (primarily eucalyptus or pine) with nectar and water sources nearby, generally near the coast.

[701] San Francisco Bay Eelgrass Inventory, June-October 2003. Prepared for Caltrans and NOAA Fisheries. Prepared by Merkel and Associates, 2003.

[702] Wyllie-Echeverria, S. and M. Fonseca. Eelgrass (*Zostera marina*) research in San Francisco Bay, California from 1920 to the Present. 2003.

A total of seven monarch butterflies were observed during the Yosemite Slough Watershed Wildlife Survey.[703] Ms. Mia Monroe, a Ranger with the Muir Woods National Monument (US National Parks Service) and co-coordinator of the Monarch Campaign for the past 15 years, was contacted in July 2008 and July 2009 to inquire about any known monarch wintering roosts that occur in the Project site. Ms. Monroe consulted with local monarch butterfly specialists and the Monarch Campaign Thanksgiving counts. The Monarch Campaign conducts surveys for peak monarch butterfly wintering population around the Thanksgiving holiday. Ms. Monroe reported there are no records of monarch butterfly autumnal (i.e., temporary bivouac site) nor over-wintering use of the Project site in the CNDDB or reported in other records, including anecdotal observations. The nearest observations of monarch butterfly roosts are at Fort Mason, the Presidio of San Francisco, and Stern Grove.[704]

Using the likelihood of occurrence definitions provided in Table III.N-5, although individual monarch butterflies were observed, the sensitive winter roosting habitat is "not likely" to occur within the Study Area.

Birds

While the CNDDB reports no occurrences of any special-status bird species in the Study Area, special-status bird species have been recorded in the Study Area during the Yosemite Slough Watershed Wildlife Survey and by Alan Hopkins, as documented in that survey's report. Special-status bird species with potential to occur on the site are described below and are also summarized in Table III.N-5. Although the harlequin duck (*Histrionicus histrionicus*), Barrow's goldeneye (*Bucephala islandica*), common loon (*Gavia immer*), yellow warbler (*Dendroica petechia*) and Vaux's swift (*Chaetua vauxi*) have all been observed within the site, these species are considered California Species of Special Concern only when breeding. [705] As they only occur within the site as non-breeders, none of them are discussed below, as they would be present only when they would not be considered Species of Concern.

*Alameda Song Sparrow (*Melospiza melodia pusillula*)*

The Alameda song sparrow is a CDFG Species of Special Concern. The Alameda song sparrow occurs only in the marshlands of the southern San Francisco Bay Region.[706] The primary range of the Alameda song sparrow extends from Coyote Creek, at the southern extremity of the Bay, northward along the west shore of South San Francisco Bay to Belmont Slough (south of the Study Area) and along the east shore to San Lorenzo. Song sparrows nest in dense riparian thickets, emergent wetlands (including salt marshes), and dense thickets of other vegetation.[707] The Alameda song sparrow uses tidal salt marsh habitats along the edge of the Bay and streams where tidal flow affects the vegetation. Candlestick Point and HPS Phase II provide potential habitat for this species in salt marshes along the shoreline, but due to the very narrow nature of tidal salt marsh in the Study Area, such habitat is marginal at best for this species. Song sparrows were observed

between January 2003 and April 2004 along Yosemite Slough, but the observed sparrows may or may not be Alameda song sparrows.[708] Observations in April may be of breeding birds although nesting has not been documented. Given the marginal quality of habitat on the site, the site's isolation from more extensive marshes that may serve as source populations for Alameda song sparrows, and the sedentary nature of Alameda song sparrows, it is possible that these are the more widespread race *gouldii* or that they represent migrants or wintering individuals from other races that occur in the region during the non-breeding season. The CNDDB does not report occurrences of Alameda song sparrow in the Study Area.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species has a "low" likelihood to occur within the Study Area.

*American Peregrine Falcon (*Falco peregrinus anatum*)*

The American peregrine falcon is a state-listed endangered species and a CDFG fully protected species pursuant to Section 3511 of the *California Fish and Game Code*; however, the California Fish and Game Commission voted to remove the species from the state endangered species list on August 6, 2009. The bird has experienced a remarkable resurgence in California and other parts of North America. This striking recovery is due in large measure to the ban on the use of DDT (a synthetic pesticide) in many places , including the United States. The peregrine has recovered in North America to the point that the USFWS removed the species from the federal Endangered Species List on August 25, 1999.[709] A pair of American peregrine falcons has nested in the Re-gunning crane on Parcel D of the Shipyard, and has raised several broods at this location over the years.[710] These birds forage widely over the entire Study Area, likely feeding primarily on rock pigeons (*Columba livia*) and waterbirds.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species is "known" to occur within the Study Area.

*Bryant's Savannah Sparrow (*Passerculus sandwichensis alaudinus*)*

Bryant's savannah sparrow is a CDFG Species of Special Concern. Bryant's savannah sparrow is a California endemic restricted to a narrow coastal strip from Humboldt Bay south to the Morro Bay; its center of abundance appears to be the San Francisco Bay area.[711] This sparrow occupies low tidally influenced habitats, adjacent ruderal areas, moist grassland within and just above the fog belt, and infrequently, drier grasslands. Adjacent to salt marshes this sparrow also occupies weedy spoil areas, canal banks, and bottomland pastures. In South San Francisco Bay, it nests mainly on levee tops grown to grasses and in areas of high pickleweed on levee banks. Bare ground, whether provided by tidal mud flats or upland interstitial areas between clumps of vegetation, appears to be an important component of occupied habitat. The Study Area provides potential habitat for this species in salt marshes along the shoreline, but because

of the very narrow nature of tidal salt marsh in the Study Area only marginal quality habitat is available. Savannah sparrows were observed between January 2003 and April 2004 along Yosemite Slough, although the observed sparrows may or may not be Bryant's savannah sparrows.[712] Observations in April 2004 may be of breeding birds although nesting has not been documented. Given the marginal quality of habitat on the site and the site's isolation from more extensive marshes that may serve as source populations for savannah sparrows, it is possible that these represent migrants or wintering individuals from other races that occur in the region during the non-breeding season. The CNDDB does not report occurrences of the Bryant's savannah sparrow bird in the Study Area.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species has a "low" likelihood to occur within the Study Area.

*Burrowing Owl (*Athene cunicularia*)*

Burrowing owl, a CDFG Species of Special Concern, is an owl that dwells in generally flat, open, dry grasslands, pastures, deserts, and shrub lands, and in grass, forbs and open-shrub stages of pinyon-juniper and ponderosa pine habitats. Burrowing owls use communal ground squirrel and other small mammal burrows for nesting and cover, as well as artificial structures such as roadside embankments, levees, and berms. They can exhibit high site fidelity, often reusing burrows year after year. Occupancy of suitable burrowing owl habitat by breeding birds can be verified at a site by observation of a pair of burrowing owls during their breeding season (March to August) or, alternatively, by the presence of molted feathers, cast pellets, prey remains (rodents, small reptiles, and large insects), eggshell fragments, or whitewash (guano), at or near a burrow. Burrowing owls are fairly tolerant of human activity near their nest burrows as long as suitable foraging habitat exists nearby. Owl populations have declined sharply in some portions of California during the past two decades (i.e., the San Francisco Bay Area, Sacramento County, San Joaquin County, etc.), but they have increased greatly in some agricultural counties (particularly Imperial). Field work for the *San Francisco Breeding Bird Atlas* in 1991-1993 did not detect breeding evidence by this species anywhere in the City.[713] The CNDDB does not report occurrences of this species in the area, but burrowing owls have been recorded previously on the site. Historically, they occurred in a rubble pile in the northeastern corner of Candlestick Point, and there have been sporadic sightings of the species in various locations on HPS as well. Breeding is not known to have occurred in the Study Area, and these individuals may all have been migrants and wintering individuals.[714] The frequency of occurrence has apparently declined in recent years, and although suitable breeding, roosting, and foraging habitat is present within the Study Area, the species does not currently breed here and occurs sporadically and in low numbers, at best.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species is "known" to occur within the Study Area.

[714] Personal Communication between from Alan Hopkins to Steve Rottenborn, July 10, 2009.

*California Brown Pelican (*Pelecanus occidentalis californicus*)*

The California brown pelican is on the verge of recovery. It has been proposed for delisting by the Fish and Game Commission[715] and also recently proposed for delisting under the FESA.[716] It is fully protected by CDFG under Section 3511 of the *California Fish and Game Code*. The California brown pelican is found in estuarine, marine sub-tidal, and marine pelagic (deep) waters along the California coast. Pelicans nest from the Channel Islands of Southern California southward along the Baja California coast and in the Gulf of California to coastal southern Mexico.[717] The pelican builds nests of sticks on the ground, typically on islands or offshore rocks. Post-breeding adults and immature birds are found along the Pacific Coast from Oregon south into Baja, Mexico. This species has been observed perching on piers within HPS Phase II, particularly the three piers in the southeastern corner of HPS Phase II, and it forages within San Francisco Bay; however, the species has never nested as far north as the Bay and nesting habitat for this species is not present in the Study Area. In addition, CNDDB does not report occurrences of California brown pelican communal roosts in the Study Area.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species is "known" to occur within the Study Area.

*Loggerhead Shrike (*Lanius ludovicianus*)*

The loggerhead shrike, a CDFG Species of Special Concern, is a common resident and winter visitor in lowlands and foothills throughout California and prefers open habitats with scattered shrubs, trees, posts, fences, utility lines, or other perches. Highest density occurs in open-canopied valley foothill hardwood, valley foothill hardwood-conifer, valley foothill riparian, pinyon-juniper, juniper, desert riparian, and Joshua tree habitats. It occurs only rarely in heavily urbanized areas, but is often found in open cropland. The *San Francisco Breeding Bird Atlas*, for which field work was conducted in 1991-1993, reported a record of possible breeding in the atlas block that included HPS and referred to a historical breeding record in the atlas block that includes Candlestick Point.[718] Low numbers of loggerhead shrikes have been observed on Candlestick Point and HPS by Alan Hopkins, and non-native grasslands provide suitable foraging habitat and on-site trees provide suitable nesting habitat for this species. However, there is no evidence of confirmed breeding in recent years, and the species currently occurs as an uncommon migrant and winter resident.[719]

Using the likelihood of occurrence definitions provided in Table III.N-5, this species is "known" to occur within the Study Area. However, this species is considered a California Species of Special Concern only when breeding. Because it is currently known to occur in the Study Area only as a non-breeder, it would not be considered a Species of Special Concern in the Study Area.

*Northern Harrier (*Circus cyaneus*)*

The northern harrier, a CDFG Species of Special Concern, prefers coastal prairies, marshes, grasslands, swamps and other open areas. Although this species primarily eats small rodents (mice and voles), amphibians, small reptiles, small rabbits, and other birds, northern harriers will eat some invertebrates as well. Northern harriers usually return to the same area to nest in consecutive years. They nest on the ground in well-concealed locations, often near low shrubs or in tall clumps of vegetation. Nesting locations are usually in abandoned fields, wet meadows, and coastal and inland marshes. Wetlands and non-native grasslands provide suitable foraging habitat for small numbers of this species on the site, and northern harriers have been observed by Alan Hopkins in the Study Area.[720] However, due to the extent of disturbance by humans and pets, the lack of extensive wetlands suitable for nesting, and the vulnerability of ground-nesting birds to predation in upland portions of the Study Area, harriers are not expected to nest there. Field work for the *San Francisco Breeding Bird Atlas* in 1991-1993 did not detect breeding evidence by this species anywhere in the City.[721]

Using the likelihood of occurrence definitions provided in Table III.N-5, this species is "known" to occur within the Study Area. However, this species is considered a California Species of Special Concern only when breeding. Because it is currently known to occur in the Study Area only as a non-breeder, it would not be considered a Species of Special Concern in the Study Area.

*San Francisco Common Yellowthroat (*Geothlypis trichas sinuosa*)*

The San Francisco common yellowthroat is a California Species of Concern and is one of four subspecies of common yellowthroat that breed in California. The breeding range of the San Francisco common yellowthroat as described by Foster is bounded by Tomales Bay on the north, Carquinez Strait on the east, and Santa Cruz County on the south, which would include the Study Area.[722] Yellowthroats are found in freshwater marshes, coastal swales, swampy riparian thickets, brackish marshes, salt marshes, and the edges of disturbed weed fields and grasslands that border soggy habitats.[723] In the San Francisco Bay region as a whole, about 60 percent of yellowthroats breed in brackish marsh, 20 percent in riparian woodland/swamp, 10 percent in freshwater marsh, 5 percent in salt marsh, and 5 percent in upland vegetation.[724] The brackish marsh in the Study Area provides potential habitat for this species, although the limited extent of such habitat limits the possibility that the species currently breeds here. Common yellowthroats were observed between January 2003 and April 2004 during surveys along Yosemite Slough, though it is unknown whether these were San Francisco common yellowthroats or migrants/wintering birds of other races.[725] Field work

for the *San Francisco Breeding Bird Atlas* in 1991-1993 did not detect breeding evidence by this species anywhere in the eastern part of the City, including the Project vicinity.[726]

Using the likelihood of occurrence definitions provided in Table III.N-5, this species has a "moderate" likelihood to occur within the Study Area.

*Short-eared owl (*Asio flammeus*)*

The short-eared owl, a California Species of Concern, is usually found in open areas with few trees such as annual and perennial grasslands, prairies, meadows, dunes, irrigated lands, and saline and fresh emergent marshes. Its prey consists of small mammals, marsh birds, insects, reptiles, and amphibians.[727] The short-eared owl will usually nest on dry ground in a depression that is concealed in vegetation; occasionally the nest will be placed in a burrow. It requires dense vegetation for roosting and resting cover. This includes tall grasses, brush, ditches, and wetlands. Open, treeless areas containing elevated sites for perching are also needed. This species was observed by Alan Hopkins on the site[728] and the Study Area provides suitable foraging habitat for this species. As a result, short-eared owls are expected to forage occasionally in low numbers on the site. However, due to the extent of disturbance by humans and pets, the lack of extensive wetlands suitable for nesting, and the vulnerability of ground-nesting birds to predation in upland portions of the Study Area, short-eared owls are not expected to nest there. Field work for the *San Francisco Breeding Bird Atlas* in 1991-1993 did not detect breeding evidence by this species anywhere in the City.[729]

- Using the likelihood of occurrence definitions provided in Table III.N-5, this species is "known" to occur within the Study Area. However, this species is considered a California Species of Special Concern only when breeding. Because it is currently known to occur in the Study Area only as a non-breeder, it would not be considered a Species of Special Concern in the Study Area.

*Tricolored Blackbird (*Agelaius tricolor*)*

The tricolored blackbird, a California Species of Concern, is a highly social, marsh-nesting bird that lives in flocks numbering from less than one hundred to many thousands. Tricolored blackbirds are permanent residents of California, but birds make extensive migrations and movements, both in the breeding season and in winter, within their restricted range.[730] Tricolored blackbirds live in large colonies, and they prefer open accessible water, a protected nesting substrate such as flooded, thorny or spiny vegetation, and a suitable foraging space providing insect prey within a few miles of nesting colonies. Nesting habitat includes cattails and bulrushes or ungrazed grasslands containing tall grasses. Other plant species that are used for nesting include young willow thickets and wild rose. This species has been observed by Alan Hopkins on the Study Area[731] and the site provides suitable foraging habitat for the species. However, no

[731] Golden Gate Audubon Society, *Final Report Yosemite Slough Watershed Wildlife Survey 2003–2004*, prepared by LSA, July 27, 2004.

suitable breeding habitat is present, no colonies are known to occur in the area, and the *San Francisco Breeding Bird Atlas* did not confirm breeding by this species anywhere in the City.[732]

Using the likelihood of occurrence definitions provided in Table III.N-5, this species is "known" to occur within the Study Area. However, this species is considered a California Species of Special Concern only when breeding. Because it is currently known to occur in the Study Area only as a non-breeder, it would not be considered a Species of Special Concern in the Study Area.

*White-tailed Kite (*Elanus leucurus*)*

The white-tailed kite is listed as a fully protected species under Section 3511 of the *California Fish and Game Code*. White-tailed kites feed on rodents, small reptiles, and large insects in fresh emergent wetlands, annual grasslands, pastures, and ruderal vegetation. They breed between February and October. Kites often roost, and occasionally nest, communally especially during the non-breeding season. Therefore, disturbance of a relatively small roost or nesting area could affect a large number of birds. The white-tailed kite can commonly be observed foraging in extensive open grasslands throughout most of the San Francisco Bay region. While white-tailed kites were not observed during surveys conducted by PBS&J biologists on the Project site, small numbers of individuals were observed during the Yosemite Slough Wildlife surveys.[733] The species is not known to nest on the site,[734] but the grasslands and ruderal habitats on the Project site provide suitable foraging habitat for small numbers of non-breeding individuals that occasionally occur there.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species is "known" to occur within the Study Area.

Terrestrial Mammals

*Western Red Bat (*Lasiurus blossevillii*)*

- The only special-status bat species potentially occurring within the Study Area is the western red bat (*Lasiurus blossevillii*). The western red bat is not known to breed in San Francisco, but the species is migratory, and red bats occur here during migration and possibly during winter. Western red bats are not colonial, and, thus, the species is expected to occur in the Study Area only in small numbers. They are known to roost in the foliage of a number of tree species, including eucalyptus. Potential habitat for this species is present within the eucalyptus and other mature trees within the Project site. However, most bat species are sensitive to human-generated disturbance. Identification of bats requires special surveys that were not conducted for this analysis. Therefore, the conservative assumption is that this species of sensitive bat is present within the Study Area.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species has a "moderate" likelihood to occur within the Study Area.

[734] Personal Communication between from Alan Hopkins to Steve Rottenborn, July 20, 2009.

Sensitive Aquatic Resources

Mollusks

*Olympia Oyster (*Ostreola conchaphila*)*

Native Olympia oysters were historically abundant in San Francisco Bay. Oyster beds are a cornerstone in the benthic habitat, improving water quality, and providing habitat complexity that favors fish and vegetation. They also provide an important link between pelagic and benthic food webs. Their function in the estuarine food web—oyster beds generally increase fish abundance and thus make up an essential part of the Essential Fish Habitat (EFH)[735]—they are considered an important resource within this EIR as only a few relict populations remain in the Bay.[736]

- Recently, small populations of native oysters have been documented within the Bay.[737,738] Detailed surveys for native oysters were not conducted as part of this Project. Suitable habitat is distributed throughout the shoreline of Study Area. Suitable substrate is solid surfaces to which the larvae can easily attach.[739] Because the larval forms of oysters are free-floating in the Bay, and a large population exists south of the Study Area at Oyster Point Marina,[740] native oysters are likely present on suitable substrate throughout the Study Area.

Fish

*Green Sturgeon (*Acipenser medirostris*)*

The southern distinct population segment of green sturgeon (including those that reside in the Sacramento River) was listed as threatened under the FESA by NMFS on April 7, 2006.[741] Green sturgeon is a long-lived, anadromous, native fish that occurs in low numbers in the San Francisco Estuary and Sacramento River. Adults spawn in freshwater rivers from British Columbia south to the Sacramento River. In the Sacramento River, spawning occurs near Red Bluff and possibly in the Feather River. Larvae develop within these freshwater systems, migrate downstream, and remain in the estuaries for between 1 and 4 years before migrating to the ocean. Mature adults move into estuaries in the spring and spawning adults move up the rivers of their origins in late spring/early summer. Post spawning adults return to the estuary before migrating back to the ocean in late fall. Sub-adult fish also are thought to enter estuaries during

summer and fall months. The Study Area is along the San Francisco Bay, which is a saltwater habitat; the Study Area does not support the necessary freshwater spawning habitat for adult fish.[742] Juvenile fish and sub-adults may rear in the adjacent waters of San Francisco Bay.

The NMFS designated critical habitat for green sturgeon on October 2009.[743] Specific areas designated as critical habitat include: coastal US marine waters within 60 fathoms depth (360 feet) from Monterey Bay, California, north to Cape Flattery, Washington, including the Strait of Juan de Fuca, Washington, to its United States boundary; the Sacramento River, lower Feather River, and lower Yuba River in California; the Sacramento-San Joaquin Delta and Suisun, San Pablo, and San Francisco bays in California; and certain coastal bays and estuaries in California, Oregon, and Washington. The areas designated comprise approximately 320 miles of freshwater river habitat, 897 square miles of estuarine habitat (including the San Francisco Bay), 11,421 square miles of marine habitat, and 135 square miles of habitat within the Yolo and Sutter bypasses. [744] Under the FESA, critical habitat includes those areas necessary to support the continued existence and recovery of this species. Critical habitat for green sturgeon includes all of San Francisco Bay. Critical habitat designations include the specific habitat and habitat functions that are necessary for the survival and recovery of the species; these are called primary constituent elements (PCEs). Within the estuarine category of critical habitat, the PCEs include food, flow, water quality, migratory pathways, depth, and sediment quality.[745] Food is an abundance of prey items, benthic invertebrates and shrimp, within the substrate upon which sturgeon can forage. Flow refers to ample movement of water within the estuary to allow adults to orient to the Sacramento River during their spawning migrations. Water quality refers to adequate levels of dissolved oxygen, salinity, and temperatures to allow for survival and growth. Water quality also includes low levels of contaminants that could affect survival or reproductive fitness. A migratory pathway refers to the fact that sturgeon migrate through the Bay to and from upstream spawning areas. The PCE for migratory pathways allows for safe and timely passage of fish between the ocean and upstream spawning areas, but it also includes localized movement of rearing and holding sturgeon within the Bay. The depth PCE refers to the variety of water depths required to provide suitable foraging, holding, and migratory areas. Sediment quality is important because sturgeons are benthic foragers (bottom feeders) and contaminant-free sediments support higher quality prey that do not affect the survival or reproductive fitness of the fish. The Study Area includes elements of all these PCEs. However, the sediment quality may be impaired by decades of industrial use, which has resulted in contamination (refer to Section III.K [Hazards and Hazardous Materials] of this EIR). This in turn probably reduces the foraging quality.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species has a "high" likelihood to occur within the Study Area.

[743]National Marine Fisheries Service (NMFS), *Endangered and Threatened Wildlife and Plants: Final Rulemaking to Designate Critical Habitat for the Threatened Southern Distinct Population Segment of North American Green Sturgeon*. 74 Federal Register 52300, October 9, 2009.
[744] Ibid.
[745] Ibid.

*Chinook Salmon (*Oncorhynchus tshawytscha*)*

Populations of Chinook salmon potentially found adjacent to the Project site fall into three Evolutionary Significant Units (ESUs): Winter-run, Spring-run, and Fall/late-Fall-run[746] Chinook salmon. The runs of Chinook are distinguished based on the timing of the adult return to freshwater on their spawning migration. At almost any time of year, there are Chinook at some life cycle stage or another within San Francisco Bay (Table III.N-3 [Life Cycle Stages and Periods of Freshwater Residency for Chinook Salmon]). The occurrence of Chinook adjacent to the Project site could involve any of those life stages. Juvenile fish are more likely to be found adjacent to the Project site than adults because they are moving downstream from their natal streams and do not have the same swimming ability as adults. Juvenile fish from the Sacramento River populations would be expected to occur in low numbers as they stray south of the Golden Gate. Small numbers of Chinook have also recently appeared in Coyote Creek and Guadalupe River, which are both tributaries to south San Francisco Bay near Alviso; these fish are derived from hatchery releases within the native range of the species, which did not include the South Bay.[747,748] Adult or juvenile fish from either of these populations would be expected to migrate through or past the Study Area on their way to and from the Pacific Ocean because the Study Area is between the Pacific Ocean and spawning sites in the South Bay. The overall likelihood of finding a substantial number of Chinook salmon within or adjacent to the Project site at any one time is relatively low because the open water of the Study Area is not considered suitable rearing habitat for either life stage. The residence time that either life stage may spend within or adjacent to the Project site is unknown.

Table III.N-3 Life Cycle Stages and Periods of Freshwater Residency for Chinook Salmon

Species	*Adult Migration (peak)*	*Spawning (peak)*	*Juvenile Freshwater Residency*	*Outmigration (peak)*
Winter Run	Dec–July (Mar)	Apr–Aug (May–June)	5–10 months	July Oct
Spring Run	Mar–Sep (May–June)	Aug–Oct (Sep)	3–15 months	Nov–Mar (Jan–Mar)
Fall Run	June–Dec (Sep–Oct)	Sep–Dec (Oct–Nov)	1–7 months	Dec–Mar
Late Fall Run	Oct–Feb (Dec)	Jan–Apr (Feb–Mar)	7–13 months	Apr–June (Dec–Mar)

SOURCE: Moyle, 2002.

Winter-run Chinook are listed as endangered under the California and federal *Endangered Species Act*s. They spawn in the Sacramento River upstream of Red Bluff Diversion Dam and are distinguishable from other Chinook runs based on the timing of both upstream migration and the spawning season (Table III.N-3). Prior to the construction of Shasta and Keswick dams in 1943 and 1955, respectively, winter-run Chinook spawned in the upper reaches of the Sacramento, McCloud, and lower Pit rivers,[749] and Battle Creek. Presently, the majority of winter-run Chinook spawning occurs on the main stem of the Sacramento River between Keswick Dam and the Red Bluff Diversion Dam.[750] Designated critical habitat extends from Keswick Dam, Shasta County (River Mile 302) to Chipps Island (River Mile 0) at the westward margin of

746 Fall and late-fall run Chinook are treated as a single ESU by NMFS.

the Sacramento-San Joaquin Delta; all waters from Chipps Island westward to Carquinez Bridge, including Honker Bay, Grizzly Bay, Suisun Bay, and Carquinez Strait; all waters of San Pablo Bay westward of the Carquinez Bridge; and all waters of San Francisco Bay (north of the San Francisco/Oakland Bay Bridge) from San Pablo Bay to the Golden Gate Bridge. Critical habitat does not extend into the Study Area.

Spring-run Chinook salmon are listed as a threatened species under the California and federal ESAs. Spring-run Chinook enter the Sacramento River between March and September and move upstream into the headwaters, where they hold in pools until they spawn between August and October. Juveniles emigrate from the tributaries from mid-November through June; however, some juveniles spend a year in the streams and emigrate as yearlings the following October.[751] Typically, spring-run Chinook salmon use mid- to high-elevation streams that provide appropriate low water temperatures and sufficient flow, cover, and pool depth to allow over summering. Spawning occurs between August and October and, depending on water temperature, emergence occurs between November and March. Although Spring-run Chinook salmon emigration is highly variable, the emigration period extends from November to early May, with up to 69 percent of young-of-the-year out migrants passing through the lower Sacramento River between mid-November and early January.[752] Designated critical habitat extends from Keswick Dam, Shasta County (River Mile 302) to Chipps Island (River Mile 0) at the westward margin of the Sacramento-San Joaquin Delta; all waters from Chipps Island westward to Carquinez Bridge, including Honker Bay, Grizzly Bay, Suisun Bay, and Carquinez Strait; all waters of San Pablo Bay westward of the Carquinez Bridge; and all waters of San Francisco Bay (north of the San Francisco/Oakland Bay Bridge) from San Pablo Bay to the Golden Gate Bridge. Critical habitat does not extend into the Study Area.

Central Valley Fall and Late Fall-run Chinook salmon are not listed under the state or federal endangered species act but are classified as a Species of Special Concern. Fall-run Chinook salmon is the most abundant ESU, documented to comprise about 92 percent of the Sacramento Basin stock over the past 10 years of available data.[753] The ESU includes all naturally spawned populations of fall-run Chinook salmon in the Sacramento and San Joaquin River basins and their tributaries, east of Carquinez Strait, California. Juvenile fall and late fall-run fish could stray into open waters within and adjacent to the Project site if they miss the entrance to the Golden Gate and the Pacific Ocean.

A small population of Chinook salmon has become established in recent years in Coyote Creek and the Guadalupe River.[754] The regulatory status of this population is unclear because the fall/late fall-run ESU only includes naturally spawned fish from upstream of Carquinez Strait. There is not an ESU that includes fish spawning within the tributaries of San Francisco Bay. These fish exhibit a fall-run pattern similar to the fall-run ESU of the Central Valley, and are apparently derived from wandering individuals, likely

hatchery-released fish, from that ESU.[755] Regardless of where they came from or what their regulatory status may be, these fish would pass the Study Area on their way to and from the ocean.

Using the likelihood of occurrence definitions provided in Table III.N-5, the spring-run, winter-run/ and fall/late fall-run of this species has a "High" likelihood to occur within the Study Area.

*Central Valley Steelhead (*Oncorhynchus mykiss*)*

Central Valley steelhead (rainbow trout) were federally listed as a threatened species in 1998[756] and this status was reaffirmed in 2006.[757] The Central Valley steelhead population is a Distinct Population Segment (DPS; aka ESU) that includes all naturally spawned populations of steelhead in the Sacramento and San Joaquin rivers and their tributaries. Final critical habitat, designated in September 2005 for this species, does not include the Study Area.[758] Critical habitat is designated by hydrologic unit, the closest of which to the Study Area is the Sacramento Delta Hydrologic Unit, over 25 miles north of the Project site.[759] Central Valley steelhead, especially juveniles, may occasionally stray into the South Bay during their migration to the ocean, but the area adjacent to the Project site is generally outside their migratory pathway.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species has a "low" likelihood to occur within the Study Area.

*Central California Coast Steelhead (*Oncorhynchus mykiss*)*

The Central California Coast DPS of steelhead is a federally threatened species.[760] This DPS includes all naturally spawned populations of steelhead from the Russian River south to, and including, Aptos Creek and includes the populations within San Francisco Bay.[761] Steelhead begin their migration from the ocean when winter rains provide large amounts of cold water for migration and spawning. Peak migration period for adult fish is in mid-winter. They typically spawn in smaller streams and tributaries to mainstream rivers. Juvenile steelhead generally spends one to three years in freshwater before migrating to the ocean.[762]

It is highly likely that both adults and juvenile steelhead from this DPS could be found adjacent to the Project site. The closest potential steelhead spawning streams in South San Francisco Bay are San Mateo Creek (approximately 10 miles south of the Study Area), Alameda Creek (approximately 16 miles south of the Study Area), and San Francisquito Creek (approximately 22 miles south of the Study Area). Other South Bay watersheds that support populations of steelhead include the Coyote Creek and Guadalupe River watersheds. Because the Study Area is between their spawning and rearing streams and the Pacific Ocean, fish from any

of these streams could be found in the Bay adjacent to the Project site during adult migrations from the Pacific Ocean to spawning sites or during juvenile migrations from their natal streams to the Pacific Ocean.

The final critical habitat designation for the Central California Coast steelhead DPS was issued on September 2, 2005.[763] The specific primary constituent elements considered in the designation were freshwater spawning sites, freshwater rearing sites, freshwater migration corridors, estuarine areas, nearshore marine areas, and offshore marine areas. The lateral extent of critical habitat in estuarine areas is the area inundated by extreme high tide. The Study Area is within the designated critical habitat for this species.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species has a "high" likelihood to occur within the Study Area.

*Longfin Smelt (*Spirinchus thaleichthys*)*

Longfin smelt were listed under the California Endangered Species account as a threatened species in March 2009. This species is endemic to the west coast of North America with small populations likely still present in the Klamath River and Russian River estuaries.[764] However, the bulk of the longfin smelt population appears to be in San Francisco Bay.[765] Adults spawn in the Sacramento-San Joaquin Estuary almost as far upstream as the City of Sacramento on the Sacramento River and to Turner Cut on the San Joaquin River.[766] Adults spawn in these upstream freshwater locations in early winter. The larval smelt are distributed downstream by natural river flow. Because of this, the higher the outflow of freshwater from the Sacramento-San Joaquin Delta, the greater the distribution of smelt in the Bay. As they mature, swimming ability improves and their distribution expands. Adults occur into the South Bay and are also found in the ocean just outside the Golden Gate.[767] This species could be found in the Study Area from spring to fall before adults return upstream to spawn.

Using the likelihood of occurrence definitions provided in Table III.N-5, this species has a "moderate" likelihood to occur within the Study Area.

*Pacific Herring (*Clupea pallasi*)*

San Francisco Bay supports a small, yet productive commercial Pacific herring fishery. Pacific herring are not protected by either the state or the federal government; however, because herring are harvested for their roe, they are an important species in the economy of the San Francisco Bay Area and their populations are closely monitored by CDFG. Pacific herring are also an important species in the ecology of San Francisco Bay because herring, along with sardines and anchovies, are a primary food source for salmon and other sport fish. Pacific herring generally enter the Bay from November through April[768] of each year

---

and spawn in intertidal and sub-tidal habitats.[769] The actual sites where Pacific herring spawn in San Francisco Bay change from year to year and spawning may occur within numerous locations around the Bay. The North Bay is typically the preferred spawning area, although limited spawning has historically been observed at San Mateo Point.[770] The preferred substrate for herring spawning is eelgrass, followed by rocky seafloors, and lastly flat surfaces such as marina pilings, retaining walls, and bulkheads along the San Francisco Bay waterfront.[771] According to NMFS, known herring spawning areas within the area immediately adjacent to the Project site include several piers and areas of shoreline both north and south of the proposed marina (refer to Figure III.N-4 [Pacific Herring Spawning Habitat]).[772] Where Figure III.N-4 shows habitat as including piers, this refers to in-water portions of those structures. Also, the mapping data left gaps between the shoreline and the delineated habitat that is an artifact of the mapping. Spawning grounds could extend to the shoreline, especially in those areas where bulkheads define a vertical shoreline. The open channel to the northwest of the proposed marina between Blandy and E streets may be used by herring even though NMFS does not map it as spawning habitat.

Essential Fish Habitat

The tidal aquatic habitats adjacent to the Project site are considered EFH by the NMFS for a species assemblage that includes anchovies, sardines, rockfish, sharks, sole, and flounder.[773,774] Areas supporting the native Olympia oyster found in San Francisco Bay are also considered EFH by NMFS because oyster beds generally increase fish abundance. A more detailed discussion of the provisions of the *Magnuson-Stevens Fisheries Conservation Act*, by which effects on EFH are regulated, is provided below in Section III.N.3 (Regulatory Framework).

Wildlife Movement

Wildlife movement activities usually fall into one of three movement categories: (1) dispersal (i.e., juvenile animals from natal areas, or individuals extending range distributions); (2) seasonal migration; and (3) local movements related to home range activities (foraging for food or water, defending territories, searching for mates, breeding areas, or cover). A number of terms have been used in various wildlife movement studies, such as "wildlife corridor," "travel route," "habitat linkage," and "wildlife crossing," to refer to areas in which wildlife move from one area to another. To clarify the meaning of these terms and facilitate the discussion of wildlife movement in this analysis, these terms are defined as follows:

FIGURE III.N-4

Candlestick Point — Hunters Point Shipyard Phase II EIR

PACIFIC HERRING SPAWNING HABITAT

- **Travel route**—A landscape feature (such as a ridgeline, drainage, canyon, or riparian strip) within a larger natural habitat area that is used frequently by animals to facilitate movement and provide access to necessary resources (i.e., water, food, cover, den sites). The travel route is generally preferred because it provides the least amount of topographic resistance in moving from one area to another. It contains adequate food, water, and/or cover while moving between habitat areas and provides a relatively direct link between target habitat areas.
- **Wildlife corridor**—A patch of habitat, usually linear in nature, that connects two or more habitat patches that would otherwise be fragmented or isolated from one another. Wildlife corridors are usually bounded by urban land areas or other areas unsuitable for wildlife. The corridor generally contains suitable cover, food, and/or water to support species and facilitate movement while in the corridor.
- **Habitat linkage**—Larger, landscape-level movement features (often referred to as "habitat or landscape linkages") can provide both transitory and resident habitat for a variety of species to a more substantial, or wider, land connection between two habitat areas. Habitat linkages allow for the periodic exchange of animals between habitat areas, which is essential to maintain adequate gene pools.
- **Wildlife crossing**—A small, narrow area, relatively short in length and generally constricted in nature, that allows wildlife to pass under or through an obstacle or barrier that otherwise hinders or prevents movement. Crossings may be manmade and include culverts, underpasses, drainage pipes, and tunnels to provide access across or under roads, highways, pipelines, or other physical obstacles. These often represent "choke points" along a movement corridor.

Surveys of the Project site did not identify any major or regional wildlife corridor/travel route. The Project site is surrounded by open water and urban development that isolate habitats in the Study Area from large expanses of similar habitats in undeveloped areas elsewhere along the San Francisco Bay shoreline and in the San Bruno Mountain State Park (approximately 2 miles to the southwest). There is localized movement, as ground-dwelling animals forage for food, mate, and move between habitat patches within the Project site. Although there is localized movement between Bayview Hill and the CPSRA, Bayview Hill is also isolated from larger expanses of habitat, and movement by mammals, reptiles, and amphibians between the site and any larger expanses of natural habitat (such as San Bruno Mountain to the southwest) is severely impeded by US-101 and other roads and urban development.

In addition, although bird flyways are not traditionally considered "wildlife movement corridors," the San Francisco Bay's wetlands and tidal lands serve as important habitat for bird species during migration through the Pacific Flyway. Many bird species use these areas as an annual stopover location for several days of rest and feeding prior to continuing migration. These habitats also provide critical staging areas for migratory species. Thus, the Study Area is a minor, but important component of the much larger Bay system that provides habitat for migratory birds.

III.N.3 Regulatory Framework

Federal

Section 404 of the Clean Water Act

Section 404 of the *Clean Water Act* (CWA) (33 *United States Code* [USC] §§ 1344) requires that a permit be obtained from the USACE prior to the discharge of dredged or fill materials into any "waters of the United States or wetlands." Waters of the United States are broadly defined in the USACE regulations to include

navigable waterways, their tributaries, lakes, ponds, and wetlands. Wetlands are defined as: "Those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that normally do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas."[775] Wetlands that are not specifically exempt from Section 404 regulations (such as drainage channels excavated on dry land) are considered to be "jurisdictional wetlands." The USACE is required to consult with the USFWS, NMFS, Environmental Protection Agency, and State Regional Water Quality Control Board (SWRCB) in carrying out its discretionary authority under Section 404.

The USACE grants three types of permits: individual, general, and nationwide. Project-specific individual permits are required for certain activities that may have a potential for more than a minimal impact and necessitate a detailed application. A permit from the USACE would be required for any placement of fill in waters of the US as part of the Project.

Section 402 of the Clean Water Act

The primary mechanism in the CWA regulating the discharge of pollutants is the National Pollutant Discharge Elimination System (NPDES), which is administered by the Environmental Protection Agency (EPA). Under the NPDES program, a permit is required from EPA or an authorized state for the discharge of any pollutant from a point source into the waters of the US (33 USC §§1342). Storm water pollution prevention plans must be prepared for construction activities as part of the NPDES permitting process.

Section 401 of the Clean Water Act

Section 401 of the CWA (33 USC §§ 1341) requires a state-issued Water Quality Certification for all projects requiring a Section 404 permit, or other federal permit or license. There are nine Regional Water Quality Control Boards (RWQCBs) across the state that issue Water Quality Certifications for various actions within their respective region. The RWQCB, San Francisco Bay Region, issues Section 401 Water Quality Certifications for the City and County of San Francisco. A Section 401 certification requires a determination that the Project will comply with all state water quality standards.

Federal Endangered Species Act (FESA)

The FESA was enacted in 1973. Under the FESA, the Secretary of the Interior and the Secretary of Commerce have the authority to list a species as threatened or endangered (16 USC 1533[c]). The FESA is administered by both the NMFS and the USFWS. The NMFS is accountable for animals that spend most of their lives in marine waters, including marine fish, most marine mammals, and anadromous fish such as Pacific salmon. The USFWS is accountable for all other federally listed plants and animals.

Pursuant to the requirements of FESA, a federal agency authorizing, funding or carrying out a project within its jurisdiction must determine whether any federally listed threatened or endangered species may be present within the Study Area and determine whether the agency's action could affect any federally listed species (16 USC 1536(a)(2), (3).) If the action would likely affect a listed species, the agency must consult with the USFWS or NMFS under Section 7 of the FESA to determine whether the action is likely

[775] US Army Corps of Engineers, *Definition of Waters of the United States*, 33 CFR 328, November 1986.

to jeopardize the continued existence of the species or result in the destruction or adverse modification of designated critical habitat (16 USC 1536(a)(2).) Project-related adverse effects to these species or their habitats are typically considered significant under CEQA and thus would require mitigation.

The USFWS Regional Office in Sacramento maintains a list of "species of concern" that receive special attention from other federal agencies (i.e., NMFS) during environmental review, although they are not protected under FESA. Project-related impacts to such species could be considered significant under CEQA Guidelines section 15380 and could require mitigation.

Section 9 of the FESA prohibits any person or federal agency from "taking" endangered or threatened wildlife. The definition of "take" includes harassing, harming, hunting, shooting, wounding, killing, trapping, capturing, or collecting, or attempting to engage in any such conduct. A notable component of this definition is the definition of "harm." "Harm" in the definition of "take" means an act that actually kills or injures protected wildlife. Such acts may include significant habitat modification or degradation where it actually kills or injures wildlife by significantly impairing essential behavior patterns, including breeding, feeding, or sheltering.

Projects that would result in "take" of any federally listed threatened or endangered species are required to obtain incidental take authorization from NMFS or USFWS through either the Section 7 (interagency consultation) process described above or Section 10(a) (incidental take permit) of FESA. The Section 7 authorization process is used to determine if a project with a federal nexus would jeopardize the continued existence of a listed species and what mitigation measures would be required to avoid jeopardizing the species. The Section 10(a) process allows take of endangered species or their habitat when no other federal government action is involved. Because the Project could affect a federally listed species and would require a federal (Section 404) permit, pursuant to Section 7 of the FESA, the USACE must initiate consultation with USFWS or NMFS prior to carrying out its discretionary authority under Section 404 of the CWA.

Migratory Bird Treaty Act (MBTA)

The federal *Migratory Bird Treaty Act* (MBTA; 16 USC, Sec. 703, Supp. I, 1989) prohibits killing, possessing, or trading in any native bird that may occur within the Study Area except in accordance with regulations prescribed by the Secretary of the Interior. It is an international treaty for the conservation and management of bird species that migrate through more than one country, and is enforced in the United States by the USFWS. This act encompasses whole birds, parts of birds, and bird nests and eggs and provides protection to over 800 species in the United States. All native birds in the Study Area are protected by the MBTA.

Marine Mammal Protection Act

The *Marine Mammal Protection Act* (MMPA) was enacted in 1972 and amended through 2007(16 USC 1631). All marine mammals are protected by the MMPA, which prohibits their take in US Waters. Take is defined in the MMPA as "harass, hunt, capture, kill or collect, or attempt to harass, hunt, capture, kill or collect" [16 USC 1631 Section 3(13)]. This is a slightly different definition than the FESA, which also encompasses "attempts" to engage in these activities. Under the MMPA, "harassment" is further defined as any action that of pursues, torments, or annoys a marine mammal and which has the potential to injure or disturb a marine mammal or marine mammal stock in the wild including alteration of behavior patterns including migration, breathing, nursing, breeding, feeding, or sheltering [16 USC 1631 Section 3(18(A))].

Species that occur within San Francisco Bay on a regular basis that are protected by the MMPA include the harbor seal and the California sea lion. The MMPA would apply to the Project, because in-water construction activities such as pile driving could harass these animals.

Magnuson-Stevens Fisheries Conservation Act and Management Act

The NMFS has the authority to implement the *Magnuson-Stevens Fisheries Conservation and Management Act* (Public Law 94-264; MSA). The *Magnuson-Stevens Act* (MSA) was amended and reauthorized on January 12, 2007, by the *Magnuson-Stevens Fisheries Conservation and Management Reauthorization Act* (PL 109-479). The MSA was put into place to promote conservation and management of the Nation's fishery resources. The MSA established the Pacific Fishery Management Council, which was tasked with creating the Pacific Coast Groundfish Fishery Management Plan (FMP).[776] The most recent amendment to the FMP was adopted by NMFS in May 2006.[777] The FMP develops recommendations for the management of groundfish fisheries, and in some cases, it contains specific fishery management recommendations. [778] In addition, the FMP addresses provisions in the MSA relating to EFH to ensure that fishery resources are managed through the regulation of EFH. The MSA defines EFH as "... those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity" [16 USC 1802 MSA Section 3(10)]. The terms in this definition have been further defined to include:[779]

- Aquatic habitat and associated physical, chemical, and biological properties that are used by fish (historically used areas may be included)
- Sediment, stream substrates, instream structure, and associated biological communities
- The habitat required to support a sustainable fishery including that particular species' place in a properly functioning ecosystem
- The habitat required to support a full life cycle for the species under consideration

The tidal aquatic habitats adjacent to the Project site are considered EFH by NMFS for a species assemblage that includes anchovies, sardines, rockfish, sharks, sole, and flounder.[780,781] Areas supporting the native Olympia oyster found in San Francisco Bay are also considered EFH by NMFS because oyster beds generally increase fish abundance. In addition, eelgrass beds are considered EFH. The NMFS consults with federal action agencies under the MSA in a process similar and often parallel to the Section 7 FESA consultation. Because the Project would modify designated EFH, consultation with NMFS under the MSA is anticipated and would be initiated by the USACE during the permitting process for the Project.

Section 10 of the Rivers and Harbors Act of 1899

Section 10 of the *Rivers and Harbors Act of 1899* (33 USC 403) gives the USACE jurisdiction over tidal waters of the US from the MHW elevation seaward (33 USC 403.382.4b). Specifically, it prohibits the construction, dredging, or fill of any navigable water without a permit from the USACE. This includes construction of breakwaters or marinas, installation of pilings, docks, or bridges, and excavation of existing substrates.

The Project would require placement of fill for bridge construction, shoreline revetments, breakwaters, installation of pilings and marina floats, and installation of gangways for access to the docks. All of these activities would be subject to the USACE jurisdiction under Section 10 of the *Rivers and Harbors Act*, and USACE authorization of these activities must be obtained through the permitting process for the Project.

State

California Endangered Species Act (CESA)

The CESA was enacted in 1984. Under the CESA, the California Fish and Game Commission has the responsibility for maintaining a list of threatened and endangered species. Pursuant to the requirements of CESA, an agency reviewing a project within its jurisdiction must determine whether any state-listed endangered or threatened species may be present in the Study Area and determine whether the Project would have an adverse effect on such species. In addition, CDFG encourages informal consultation on any project that may impact a candidate species. Peregrine falcons nest within the Study Area, as noted above, and are listed as endangered under the CESA, although the species is proposed to be delisted.

Section 2080 of the *California Fish and Game Code* prohibits "take" of any species that the commission determines to be an endangered species or a threatened species. Take is defined in Section 86 of the *California Fish and Game Code* as "hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill." Sections 2081(b) and (c) of the *California Fish and Game Code* allow CDFG to issue an incidental take permit for a state-listed threatened or endangered species only if specific criteria are met, such as take incidental to an otherwise lawful activity. CESA emphasizes early consultation to avoid potential impacts to rare, endangered, and threatened species and to develop appropriate mitigation planning to offset project-caused losses of listed species populations and their essential habitats.

Fish and Game Code—Sections 1602, 3503, 3503.5, 3511, 3513, 4150, 4700, 5050, and 5515

California Fish and Game Code Section 3503 states that it is unlawful to take, possess, or needlessly destroy the nest or eggs of any bird, except as otherwise provided by the code. Birds of prey are further protected under *California Fish and Game Code* Section 3503.5, which states that "it is unlawful to take, possess, or destroy any birds in the order Falconiformes or Strigiformes (birds of prey) or to take, possess, or destroy the nest or eggs of any such bird, except as otherwise provided by this code or any regulation adopted pursuant thereto." Construction disturbance during the breeding season could result in the incidental loss of eggs or nestlings, or otherwise lead to nest abandonment. Disturbance that causes nest abandonment and/or loss of reproductive effort is considered take by CDFG. Similarly, Section 4150 of the *California Fish and Game Code* describes protections for nongame mammals.

California Species of Special Concern is a designation used by the CDFG for some declining wildlife species that are not state candidates for listing as threatened or endangered. This designation does not provide legal protection but signifies that these species are recognized as having special status by the CDFG. Under CEQA Guidelines (Section 15380), potential impacts to these species must be assessed.

California laws relating to Fully Protected species (i.e., Section 3511) were among the first attempts in the nation to provide additional protection to animals that were rare or faced possible extinction, predating even the FESA. Most fully protected species have also been given additional protection under more recent laws and regulations, and many have been listed under state and federal versions of the FESA. Fully Protected species (such as the peregrine falcon and white-tailed kite) may not be taken or possessed at any time and no licenses or permits may be issued for their take except for collecting these species for necessary scientific research and relocation of the bird species for the protection of livestock. Four sections of the *California Fish and Game Code* list 37 fully protected species (*California Fish and Game Code* Sections 3511, 4700, 5050, and 5515). Each of these statutes (1) prohibits take or possession "at any time" of the species listed in the statute, with few exceptions, (2) states that no provision of this code or any other law shall be construed to authorize the issuance of permits or licenses to "take" the species, and (3) states that no previously issued permits or licenses for take of the species "shall have any force or effect" for authorizing take or possession.

Section 1602 of the *California Fish and Game Code* requires a Streambed Alteration Agreement for any activity that may alter the bed and/or bank of a lake, stream, river, or channel. Typical activities that require a Streambed Alteration Agreement include excavation or fill placed within a channel, vegetation clearing, structures for diversion of water, installation of culverts and bridge supports, cofferdams for construction dewatering, and bank reinforcement. A Streambed Alteration Agreement would be required as part of the permitting process for this Project.

Porter-Cologne Water Quality Control Act

The *Porter-Cologne Water Quality Control Act* (California Water Code Sections 13000 et seq.) charges the SWRCB and the nine RWQCBs statewide with protecting water quality throughout California. Typically, the SWRCB and RWQCB act in concert with the USACE under Section 401 of the *Clean Water Act* in relation to permitting fill of federally jurisdictional waters. The US Supreme Court has acted to limit the regulatory jurisdiction of the USACE under Section 404 of the *Clean Water Act*.[782] This action did not limit the State's regulatory jurisdiction over Waters of the State.[783] Waters of the State are defined in Section 13050(e) of the *Porter-Cologne Water Quality Control Act* as "…any surface water or groundwater, including saline waters, within the boundaries of the state."

Wetlands are delineated in accordance with methodology presented in the 1987 *Corps of Engineers Wetlands Delineation Manual*[784] and *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West*

[782] United States Supreme Court (USSC), *Solid Waste Agency of Northern Cook County v. US Army Corps of Engineers*. 531 US 159(2001), also known as the "SWANCC decision."
[783] Guzy, G.S. and R.J. Andersen., *Memorandum from the Corps regarding: Supreme Court ruling concerning CWA jurisdiction over isolated waters.* Website: http://www.spn.usace.army.mil/regulatory/ swancc.pdf, 2001.
[784] Environmental Laboratory*, Corps of Engineers Wetlands Delineation Manual.* Technical Report Y-87-1, US Army Engineer Waterways Experiment Station. Vicksburg, Miss., 1987.

Region.[785] Applicants have this delineation verified by the USACE and, in cases where an area meets the criteria to be considered a wetland, but the USACE does not have jurisdiction, the applicant is referred to the appropriate RWQCB. For the Study Area, the San Francisco Bay Regional Water Quality Control Board (SFRWQCB) could exercise its jurisdiction over wetlands where a project does not require a federal permit, but involves removal or placement of material into Waters of the State. The USACE has indicated that the waters and wetlands potentially impacted by the Project are subject to its jurisdiction. A Section 401 clean water certification or waiver would be required as part of the permitting process for this Project.

The McAteer-Petris Act (California Government Code 66600–66682)

The *McAteer-Petris Act* created the San Francisco Bay Conservation and Development Commission (BCDC) in 1965. BCDC's mission is the preservation of San Francisco Bay from indiscriminate filling. BCDC's first task was compilation of a comprehensive study of the Bay and determination of how future development of the Bay should occur. This effort resulted in the San Francisco Bay Plan in 1968. In 1969 the findings and policies of the Bay Plan were incorporated into the *McAteer-Petris Act*, which was amended making BCDC a permanent state agency. The Bay Plan continues to evolve and remains the guiding document for BCDC's actions. Section 66610 of the *McAteer-Petris Act* establishes the boundaries of San Francisco Bay in relation to BCDC's jurisdiction. Essentially, all areas below the mean high tide line and an area within a shoreline band that extends landward for 100 feet from the mean high tide line are subject to their jurisdiction. Section 66632 of the *McAteer-Petris Act* establishes the permitting process for projects that would place fill in, on, or over any part of BCDC's jurisdiction as defined in Section 66610. Some aspects of the Project would be in the water or within the shoreline band and, therefore, subject to BCDC's jurisdiction.

■ Regional

Long Term Management Strategy for the Placement of Dredged Material in the San Francisco Bay Region (LTMS) Management Plan

In 1999, under the authority of the federal FESA, NOAA Fisheries and the USFWS, and the CDFG, under the CESA, completed a programmatic consultation for the Long Term Management Strategy for the Placement of Dredged Material in the San Francisco Bay Region (LTMS) Management Plan[786]. NOAA Fisheries, USFWS and CDFG concluded that the LTMS program was not likely to jeopardize the continued existence of listed species under their jurisdiction. The respective biological opinions provided an incidental take statement, which authorized the take of listed species that may inadvertently occur during dredging and dredged material disposal activities that adhere to the environmental work windows set forth in the LTMS Management Plan. Therefore, permitted dredging activities that conform to the Environmental Work Windows can be completed without the need to consult with the resource agencies under the FESA and the CESA. Any project proposing to conduct dredging activities outside of the LTMS environmental work windows is required to undertake either informal or formal consultation with the appropriate resource agencies (NOAA Fisheries, USFWS, and CDFG).

San Francisco Bay Trail Plan

Refer to Section III.A Land use and Plans for a description of the Bay Trail Plan. Environmental Protection Policies relevant to the Project are listed below.

Environmental Protection Policies[787]

23. The Committee is aware of the ecological value of wetlands; in many cases, they provide habitat for a variety of endangered species. In the San Francisco Bay Area, these areas serve as a vital link in the Pacific flyway for feeding, breeding, nesting and cover for migratory birds. To avoid impacts in wetlands habitats, the Bay Trail should not require fill in wetlands, and should be designed so that use of the trail avoids adverse impacts on wetland habitats.
24. Future support facilities serving the Bay Trail should be designed and constructed in such a manner that they do not impact fish and wildlife resources, especially wetlands. These facilities should be located and designed in a way that no fill of wetlands will be required.
26. The path will not always follow the Bay shoreline; inland reaches may be more appropriate, especially for bicycle travel, in some parts of the San Francisco Bay region.
28. Where the alignment of the Bay Trail may more appropriately be located away from the shoreline in order to protect particularly sensitive habitats, access to shoreline areas may be possible by connecting the Bay Trail to existing loop trails and other interpretive facilities. These access points should be planned and designed to make clear the distinction between the continuous Bay Trail and the interpretive trail. (Features may include different trail surfaces, marked entry points to interpretive areas, expanded facilities for education and shoreline interpretation, signage, regulation and enforcement of regulations.)
29. Provision of land or funds for Bay Trail planning or construction shall not be considered mitigation for wetland losses.

Candlestick Point State Recreation Area General Plan

Refer to Section III.A Land Use and Plans for a description of the CPSRA GP. The following excerpt is related to natural resource management:[788]

> It is the policy of the department to protect the scenic values and to enhance, manage, and protect the biotic and natural resources of the area, while fully realizing the potential of the area for fulfillment of outdoor recreation needs. A wetland restoration and management plan shall be developed for the area north and east of the extension of Yosemite Avenue to the Bay, an area known as the Nature Area. The plan shall include provisions for natural restoration and removal of debris, design of a shoreline configuration that provides a healthy intertidal action, revegetation, and wildlife habitat enhancement. This plan shall be developed in coordination with local, Bay protection, and wildlife agencies.

San Francisco Bay Plan

Refer to Section III.A Land Use and Plans for a description of the Bay Plan. A summary of the policies related to biological resources are provided below.

[787] Bay Trail Plan. 1999. Electronic file: http://baytrail.abag.ca.gov/baytrailplan.html#designguidelines. July 30.

Policies Concerning Fish, Other Aquatic Organisms and Wildlife in the Bay, Tidal Marshes and Tidal Flats Around the Bay, and Subtidal Areas in the Bay [789]

The SFBCDC shall protect native fish species, other aquatic organisms, other listed wildlife species and their specific habitats under the *California Endangered Species Act* or federal *Marine Mammal Protection Act* within the Bay's tidal marshes, tidal flats, and subtidal habitat. To the greatest extent feasible, specific habitats such as tidal marsh, tidal flats, and subtidal habitats shall be conserved, restored, and increased. Specific habitats that are needed to conserve, increase or prevent the extinction of any native species, species threatened or endangered, species that the CDFG has determined are candidates for listing as endangered or threatened under the California *Endangered Species Act*, or any species that provides substantial public benefits, should be protected, whether in the Bay or behind dikes. In reviewing or approving habitat restoration programs the SFBCDC should follow the recommendations in the Baylands Ecosystem Habitat Goals and provide a diversity of habitats for native aquatic and terrestrial plant and animal species. For projects that may adversely affect an endangered or threatened plant, fish, other aquatic organism or wildlife species the SFBCDC should consult and give appropriate consideration to the recommendations of the California Department of Fish and Game and the US Fish and Wildlife Service or the National Marine Fisheries Service and not authorize projects that would result in the "taking" of any plant, fish, other aquatic organism or wildlife species listed as endangered or threatened pursuant to the state or federal endangered species acts, or species that are candidates for listing under the CESA, unless the project applicant has obtained the appropriate "take" authorization from the US Fish and Wildlife Service, National Marine Fisheries Service or the California Department of Fish and Game. However, the SFBCDC may permit a minor amount of fill or dredging in wildlife refuges, shown on the Plan Maps, necessary to enhance fish, other aquatic organisms and wildlife habitat or to provide public facilities for wildlife observation, interpretation and education.

Policies Concerning Shoreline Protection around the Bay[790]

New shoreline erosion control projects and the maintenance or reconstruction of existing erosion control facilities should be authorized if *(a)* the project is necessary to protect the shoreline from erosion; *(b)* the type of the protective structure is appropriate for the project site and the erosion conditions at the site; and *(c)* the project is properly designed and constructed. Professionals knowledgeable of the Commission's concerns, such as civil engineers experienced in coastal processes, should participate in the design of erosion control projects.

Policies Concerning Dredging in the Bay[791]

Dredging and dredged material disposal should be conducted in an environmentally and economically sound manner. Dredgers should reduce disposal in the Bay and certain waterways over time to achieve the LTMS goal of limiting in-Bay disposal volumes to a maximum of one million cubic yards per year. The LTMS agencies should implement a system of disposal allotments to individual dredgers to achieve this goal only if voluntary efforts are not effective in reaching the LTMS goal. In making its decision regarding disposal allocations, the Commission should confer with the LTMS agencies and consider the need for the dredging and the dredging projects, environmental impacts, regional economic impacts, efforts by the dredging

[789] SFBCDC, San Francisco Bay Plan, Reprinted February 2008.
[790] Ibid.
[791] Ibid.

community to implement and fund alternatives to in-Bay disposal, and other relevant factors. Small dredgers should be exempted from allotments, but all dredgers should comply with the SFBCDC policies.

Local

Yosemite Slough Restoration Plan

The Yosemite Slough Restoration Plan (2005) was developed on behalf of the State Parks Department, in accordance with the CPSRA GP. The restoration of Yosemite Slough would create the largest contiguous wetland area in San Francisco. The restoration project would help restore essential wildlife habitat, improve water quality, and prevent erosion along the shoreline of the City—an area of the bay where tidal wetlands have been most impacted and suffered the greatest loss due to urbanization.

Goals and objectives of the restoration include the following:

- Increase the area subject to tidal influence by excavating three areas that were formerly part of San Francisco Bay.
- Restore habitat diversity by adding 12 acres of tidally influenced wetlands and marsh area and remove chemically impacted soils from upland areas to improve the quality of existing habitat.
- Improve habitat for special-status species (i.e., western snowy plover and double-crested cormorants) by creating two nesting islands.
- Improve the quality of life for the surrounding community by creating a clean, beautiful local park for viewing wildlife habitat.
- Create an environmental area that local schools can use for field trips.
- Connect to the Blue Greenway, an important effort to build 13 miles of Bay Trail along the southern waterfront of the San Francisco Bay Trail.

City of San Francisco General Plan

The following goals and policies related to biological resources protection are included in the Environmental Protection Element of the *San Francisco General Plan*, and are relevant to the Project:

<u>General</u>

Objective 1 Achieve a proper balance among the conservation, utilization, and development of San Francisco's natural resources.

- Policy 1.1 Conserve and protect the natural resources of San Francisco.
- Policy 1.2 Improve the quality of natural resources.
- Policy 1.3 Restore and replenish the supply of natural resources.
- Policy 1.4 Assure that all new development meets strict environmental quality standards and recognizes human needs.

<u>Bay, Ocean, and Shorelines</u>

Objective 3 Maintain and improve the quality of the bay, ocean, and shoreline areas.

- Policy 3.1 Cooperate with and otherwise support regulatory programs of existing regional, state, and federal agencies dealing with the Bay, Ocean, and Shorelines.

Policy 3.2 Promote the use and development of shoreline areas consistent with the General Plan and the best interest of San Francisco.

Land

Objective 7 Assure that the land resources in San Francisco are used in ways that both respect and preserve the natural values of the land and serve the best interests of all the City's citizens.

Policy 7.3 Require that filling of land adhere to the highest standards of soils engineering consistent with the proposed use.

Flora and Fauna

Objective 8 Ensure the protection of plant and animal life in the City.

Policy 8.1 Cooperate with and otherwise support the California Department of Fish and Game and its animal protection programs.

Policy 8.2 Protect the habitats of known plant and animal species that require a relatively natural environment.

Policy 8.3 Protect rare and endangered species.

San Francisco Municipal Code

Urban Forestry Ordinance

The City provides protection for trees around the City by way of its Urban Forestry Ordinance (Ord. 165-95, App. 5/19/95), Article 16, Sections 806 (Planting and Removal of Street Trees) through 810 (Significant Trees) of the *Public Works Code*. "Significant trees" are defined as trees within 10 feet of a public right-of-way that also meet one of the following size requirements: 20 feet or greater in height; 15 feet or greater in canopy width; or 12 inches or greater diameter of trunk measured at 4.5 feet above grade. Among the factors considered in the removal of significant trees are the following: their size, age, and species; visual and aesthetic characteristics; cultural or historic characteristics; ecological and location characteristics. Street trees are also protected by the City's Urban Forestry Ordinance and both require a permit for removal. The ordinance also provides a process for designating trees as landmark trees, and protects significant, landmark, and street trees during construction activities. This ordinance applies to limited areas of the Project site where there are significant trees, street trees, and/or landmark trees.

Planning Code

Section 143 of the San Francisco Planning Code requires the installation of one street tree for each 20 feet of property frontage along each street or alley, with any remaining fraction of 10 feet or more of frontage requiring an additional tree for the owner or developer of a new or relocated building, or a building with 20% or more floor area expansion in specified districts.[792] This ordinance applies to the R, SPD, RSD, NC, C-3, DTR, MUG, MUO, MUR, UMU, SLR, SLI, and SSO Districts.

[792] Amended by Ord. 414-85, App. 9/17/85; Ord. 69-87, App. 3/13/87; Ord. 115-90, App. 4/6/90; Ord. 298-08, File No. 081153, App. 12/19/2008.

III.N.4 Impacts

Significance Criteria

The City and Agency have not formally adopted significance standards for impacts related to biological resources, but generally consider that implementation of the Project would have significant impacts if it were to:

N.a Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS.

N.b Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, and regulations or by the CDFG or USFWS.

N.c Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the *Clean Water Act* (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means.

N.d Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites.

N.e Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance.

N.f Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan.

Analytic Method

As mentioned in Section III.N.2 (Setting), PBS&J staff biologists reviewed existing studies of the Project site and conducted reconnaissance-level surveys of the Project site on August 9, 2007, May 5, 2008, and July 8, 2008.

The analysis provided below considers the potential direct, indirect, and cumulative effects of construction and implementation of the Project described in Chapter II, including both on-site and off-site impacts. Potential impacts are analyzed using information identified in Chapter II, the environmental setting for biological resources, results of literature and field surveys, and the adequacy of on-site habitat for potentially occurring special-status species, and comparing this information to the Significance Criteria that were identified in the previous section. In general, impacts are separated by plan element (i.e., Candlestick Point and HPS Phase II) and are indicated by an "a" and "b," respectively, in the impact number. In addition, several impacts contain separate discussions of the proposed bridge over Yosemite Slough.

Identifying the impacts to biological resources that would result from construction of the CP/HPS Project is complicated by the fact that future remediation activities would modify existing site conditions before some CP/HPS Project components are constructed. As a result, the "baseline conditions" for the purpose of the Settings section above (i.e., existing conditions observed during field surveys conducted in the preparation of this EIR, plus other data collected or research conducted within the Study Area since 2003) are not necessarily the conditions that would be present when Project components are constructed. For example, on Parcels E and E-2, it is expected that remediation by the Navy would result in the removal

and/or capping of contaminated materials and construction of a shoreline revetment that would prevent erosion of materials on these parcels. These remediation activities (including revetment construction) would result in impacts to most of the wetlands that have been identified on Parcels E and E-2. As mitigation of these impacts, the Navy has proposed constructing new wetlands in the southwestern portion of HPS after remediation efforts are completed. Although the CP/HPS Project may construct the Yosemite Slough bridge and its approaches before the Navy's remediation efforts are concluded, other portions of Parcels E and E-2 are not expected to be improved as part of this Project until the Navy has completed its removal of radiological contamination. As a result, when CP/HPS improvements are made, wetlands on Parcels E and E-2 may be limited to the Navy's wetland mitigation site, with the remaining wetlands impacted by the Navy's fill and the revetment. To adequately characterize the impacts of the CP/HPS Project to biological resources, impacts to potentially affected resources (such as wetlands) are analyzed under two scenarios: assuming construction of Project improvements occurs prior to completion of Navy remediation activities, and assuming Navy remediation occurs first.

Impacts to special-status species would be significant (in the absence of mitigation) if the Project would adversely affect any of the following: (1) a species listed as threatened or endangered by the state or federal government at the time the Draft EIR is published; (2) a major population or subpopulation of a species that would result in the regional decline of this species; (3) a relatively large number of individuals within a population that is considered rare or declining; (4) a species' metapopulation (i.e., if one of only a few known populations occurs in the impact zone, or if the species has extremely narrow habitat requirements); or (5) a habitat type or vegetation community in regional decline or that is regionally endemic and is recognized as such by the local, state, or federal agencies identified in the Setting section. As discussed in the Setting section, those species or habitats with a "Not Likely," or "Absent" likelihood of occurrence in Table III.N-5 will not be addressed further as they are not expected to occur on the site or be affected by the Project.

Impacts to sensitive or rare species would be less than significant, even without mitigation, if they are not expected to substantially affect species or populations because (1) a relatively small number of non-listed individuals would be impacted; (2) the number of individuals of a non-listed species to be impacted represent a very small fraction of regional populations due to the species' regional abundance; (3) recovery and conservation efforts are documented to adequately conserve the species or habitat, and impacts would not affect the recovery or conservation of this species or habitat; or (4) the species or habitat is locally common and fairly abundant in the region.

This section presents Project Impacts at the conclusion of the discussion of individual impacts at Candlestick Point and HPS Phase II, beginning with Impact BI-22 and concluding with Impact BI-26.

Construction Impacts

Impact BI-1: Regional Conservation Plans

Impact BI-1 **Implementation of the Project would not conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan. (No Impact) *[Criterion N.f]***

There are no adopted Habitat Conservation Plans, Natural Community Conservation Plans, or other approved local, regional, or state habitat conservation plans that cover the Study Area. Therefore, the Project would not conflict with a Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan. Consequently, no impact to such plans would occur. No mitigation is required.

Impact BI-2: Common Species and Habitats

Impact BI-2 **Implementation of the Project would not have a substantial adverse effect, either directly or through habitat modifications, on any common species or habitats through substantial interference with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites. (Less than Significant) *[Criterion N.d]***

As listed in the Setting section, numerous common plant and wildlife species occupy the Study Area. Common wildlife includes a number of species of invertebrates, reptiles and amphibians, birds, and mammals (terrestrial and aquatic). Common aquatic resources include many species of fish, shellfish, and mollusks. Common plant communities include non-native annual grassland and landscaped areas/ornamental plants. Common species and habitats would be affected through the removal and construction of buildings, removal of trees, shoreline improvements, installation of trails, roads, and other facilities, construction and operation of the stadium and Yosemite Slough bridge, increased foot and vehicular traffic, installation of towers, and operation of stadium lights. In addition, an increase in trash, particularly food waste, could potentially subsidize nuisance species such as common ravens (*Corvus corax*), American crows (*Corvus brachyrhynchos*), raccoons, rats, and feral cats, which in turn could increase predation on more sensitive wildlife species. As a result, some common habitats would be reduced in extent, and some common species would decline in abundance as a result of the Project. However, the Project's impact to common species and habitats would not be substantial. These species/habitats are abundant throughout the San Francisco Bay region, and the Project site supports an extremely small proportion of the regional abundance of these resources. Further, the abundance of many of these species on the Project site itself is relatively low due to the extent of developed/urban land uses on the site, the long history of disturbance of the site, the intensive nature of such disturbance in some areas (e.g., where remediation activities on HPS are occurring or have recently occurred), and the site's isolation from more extensive areas of natural habitat by the Bay and by urban development in surrounding areas. Those species that are present on the site in higher numbers consist primarily of species that are well adapted to urban or heavily disturbed areas. Consequently, any impacts of the Project on common species and habitats would have a negligible effect on regional population and would thus be less than significant. No mitigation is required.

The habitat disturbance caused by the Project would result in a less-than-significant impact to regionally common species and habitats, and, in addition, the Project proposes multiple measures to further avoid and minimize impacts to common vegetation communities and wildlife species, and to enhance habitat conditions for a number of species, such as migratory birds. Specifically, the Project includes implementation of a Draft Parks, Open Space, and Habitat Concept Plan[793] (provided in Appendix N3 [Draft Parks, Open Space, and Habitat Concept Plan] to this EIR) that would take advantage of opportunities for enhancing the ecological functions and values of the parks and open space areas on the Project site. These enhancement measures would focus on areas outside the CPSRA, since the Project would neither impact directly, nor have control over enhancements in, the portion of the CPSRA that is not subject to the land transfer agreement. However, the Draft Parks, Open Space, and Habitat Concept Plan would suggest enhancements that would provide ecological benefits within the CPSRA, should State Parks decide to implement them. Some of the measures that would be included in the Draft Parks, Open Space, and Habitat Concept Plan, and that would be implemented on the Project site, include:

- **Control of non-native invasive species:** The Project site is currently dominated by non-native plants, and several are particularly invasive, having the potential to expand over large areas and significantly reduce the ecological value provided by the proposed habitat enhancements. Invasive, non-native species would be removed during initial habitat enhancement efforts, and monitoring and ongoing removal/control would be implemented to ensure against the re-establishment and spread of these species on the Project site.
- **Restoration of grasslands:** To maintain grassland-associated wildlife species on the site, grasslands extensive enough to support such species would be maintained and enhanced through the restoration of native grasses. Such grassland habitat would not be well manicured or regularly mown. No trees would be planted within designated grassland management areas, and shrub cover would be limited to a few small, scattered patches of low-statured coastal scrub plants, which will provide cover for wildlife that may otherwise forage in the grasslands. Native-dominated grassland habitat would be created, which would result in a net gain for the site.
- **Increase in tree/shrub cover:** Numerous trees (approximately 10,000 net new trees, which is more than four times the number currently present on the Project site) and shrubs (particularly natives) would be planted and maintained to provide cover for mammals, reptiles, and amphibians and enhance habitat suitability for birds. The trees would be planted at the Project site and in the community, and the shrubs would be planted at the Project site. Trees and shrubs would be particularly beneficial as foraging habitat for Neotropical and other long-distance migrant birds. Increases in foliage height diversity and vegetation volume resulting from the planting of numerous trees and shrubs on the site, most of which currently supports little woody vegetation, would result in increases in the diversity and abundance of breeding and migratory birds. While native vegetation shall be favored, site-appropriate non-native trees and shrubs that provide food or structural resources that are particularly valuable to native wildlife may also be considered.
- **Maintenance of habitat connectivity:** Roads, trails, and buildings would interrupt habitat connectivity to some extent. However, park planning and maintenance/landscaping of open space areas can maintain connectivity within the site for less mobile animals such as mammals, reptiles, and amphibians through the wildlife-friendly design of potential obstacles (i.e., fences, walls, and curbs), maintenance of a vegetated band along the shoreline, and planting of vegetative cover that provides refugia for dispersing animals.

[793] Lennar Urban, *Draft Parks, Open Space, and Habitat Concept Plan,* November 2009.

- **Maintenance of refugia for waterbirds:** In planning for future trails, vistas, and other features/facilities expected to concentrate human activities along the waterfront, at least one shoreline area where waterbirds can roost at high tide would remain removed from trails or other shoreline access points for humans. In addition, the bases of the three piers in the southeastern corner of HPS Phase II would be removed to prevent mammals from accessing these piers, and the piers would be left in place to provide roosting sites for gulls, cormorants, pelicans, and terns.
- **Provision of nest boxes:** Nest boxes for birds would be placed in appropriate locations throughout parks and open space areas.

With implementation of the Draft Parks, Open Space, and Habitat Concept Plan, many wildlife species would benefit from the removal of invasive species, enhancement, restoration, and management of habitats such as grasslands and wetlands, and the planting of numerous trees and shrubs in areas that are currently highly degraded or disturbed. Specifically, extensive planting of native vegetation would enhance the vegetation community and provide areas of enhanced habitat for common butterflies, birds, small mammals, reptiles, and amphibians on the Project site. For most species, the benefits of such enhancements would accrue to local, rather than regional, populations, as there is no substantive dispersal of most wildlife species between the site and off-site areas. However, in the case of migratory birds, the Project would result in a net benefit that would have regional or Flyway-level implications, as the Project would enhance foraging habitat that is used by birds breeding and wintering in areas far from the Study Area. Further, the Draft Parks, Open Space, and Habitat Concept Plan would identify enhancement opportunities within open space areas that can be beneficial to other common species or habitats. A discussion of potential effects of the Project on common species by wildlife type is included below.

Invertebrates

Of 14 butterfly species recorded on the Project site during the Yosemite Slough Watershed Wildlife Survey, 13 species are common and widespread and are associated with host plants that are also widespread. These butterflies would benefit from increased habitat and foraging opportunities within the proposed native habitats and landscaping plantings as a result of the Project. The western pygmy blue, which was recorded infrequently (no more than one individual on a given survey), is associated with salt marshes and is, therefore, of more limited distribution. Nevertheless, this species is found in salt marshes throughout the San Francisco Bay area and was recorded very infrequently during the Yosemite Slough Watershed Wildlife Survey. As a result, the Project would have a negligible effect on regional populations of the species, and impacts to this and other butterfly species would be less than significant. The Project would maintain and enhance habitat for the pygmy blue through restoration, creation, or enhancement of salt marsh habitat along the shoreline. As a result of salt marsh restoration on the outboard side of revetments on portions of Candlestick Point and HPS Phase II, the Project is expected to create at least as much salt marsh habitat as it impacts.

Reptiles and Amphibians

The Project would maintain habitat for all five of the reptiles (southern alligator lizard, western fence lizard, gopher snake, ring-necked snake, and western garter snake) and the single amphibian (California slender salamander) recorded on the Project site by the Yosemite Slough Watershed Wildlife Survey. Providing additional ground cover (i.e., shrubs) would improve habitat in some areas, especially in HPS Phase II, which has been subjected to intensive disturbance from remediation efforts.

Local abundance of these species may decline in some areas due to a reduction in dispersal (resulting from trails, roads, and increased vehicular traffic and human presence) and possibly increased vehicular mortality, but all six of these species are regionally abundant, and the Project's impacts would have a negligible effect on regional populations. In addition, the new and improved parkland components of the Project would provide new and/or enhanced habitat for reptiles and amphibians, which would be a localized beneficial impact in portions of the site.

Birds

Of 118 bird species observed during the Yosemite Slough Watershed Wildlife Survey, 51 (43 percent) were represented by a maximum count (the maximum number of individuals recorded on a given survey) of 5 or fewer, and thus use the Project site in low numbers. The most abundant wildlife species recorded were waterbirds. Project impacts to waterbird habitat within the Yosemite Slough bridge footprint would be mitigated by restoration on site or off site, as discussed under mitigation measure MM BI-4a.1 below. Increased human use of the Project site may reduce abundance in aquatic habitats along the immediate shoreline, but ample aquatic habitat is present around the Project site, and, even without restoration, no substantial changes in common waterbird abundance (particularly relative to regional populations) are expected as a result of the Project.

Of the 57 species of landbirds recorded, only 20 were represented by maximum counts of 10 or more, indicating that most landbirds use the study area only in low numbers. In addition, most of these species are regionally abundant species adapted to a variety of habitat types, including the disturbed, non-native dominated habitats that currently occupy most of Candlestick Point and HPS Phase II. Although many landbird species would increase in abundance due to the provision of much more extensive trees and shrubs than are currently present, a few regionally abundant landbirds associated with extensive grasslands and weedy areas (such as meadowlarks and wintering grassland sparrows) may fluctuate in abundance within the Project site. However, incorporation of grasslands in open space areas and restoration of suitable foraging habitat on portions of the Project site would maintain habitat for these species on the site by ensuring that there is habitat for small birds, reptiles, mammals, and insects, which are the primary prey for the locally occurring raptor species.

The Project would result in a net benefit to many avian species. The Project would include approximately 105 acres and 232 acres of parkland and open space improvements at Candlestick Point and HPS Phase II, respectively. Although portions of this parkland may serve primarily recreational purposes, parks in the Project area would provide an opportunity for planting of trees and shrubs that would be used by numerous birds. For example, the 82-acre[794] Grasslands Ecology Park on the southern portion of HPS would be designed and landscaped to provide a variety of habitats, including extensive grasslands as well as a mosaic of trees, shrubs, and other vegetation. A Draft Parks, Open Space, and Habitat Concept Plan, which is required by mitigation measure MM BI-7b below, would include the planting of approximately 10,000 net new trees (more than four times the number currently present in the Project area), in addition to shrubs and other vegetation, which would serve as perching, roosting, nesting, and foraging sites for a variety of birds. The trees would be planted at the Project site and in the community, and the shrubs would be planted

[794] This acreage reflects the area of parklands that would be suitable for on-site species, and represent only a portion of the total new park lands that would be created by the Project.

at the Project site. These new and improved Project components would provide both raptor foraging opportunities and enhanced habitat for certain raptor prey species that could result in higher prey base for raptors. Some waterbirds (i.e., gulls, terns, cormorants, and pelicans) would benefit from the enhanced roost sites offered by the proposed three piers, which would provide nesting and roosting sites that would no longer accessible to mammalian predators. Neotropical and other long-distance migrants, the landbird group using the site that is of greatest conservation concern, would receive a considerable net benefit from the Project. Increases in foliage height diversity and vegetation volume resulting from the planting of numerous trees and shrubs on the site, most of which currently supports little woody vegetation, would result in increases in the diversity and abundance of both breeding and migratory birds.[795,796,797] Well-vegetated sites nearby, such as Golden Gate Park and Coyote Point, provide much higher density and structural diversity of vegetation than is currently present on HPS Phase II and most of Candlestick Point, and these locations are known by birders to support high species diversity and abundance of birds, including Neotropical and other long-distance migrants.[798] With the Project's revegetation component and addition of new parklands, the Project would provide a net enhancement of breeding, wintering, and migratory stopover habitat for birds.

Mammals

Of the ten mammal species recorded in the Study Area during the Yosemite Slough Watershed Wildlife Survey, three are non-natives (domestic dog, domestic cat, and Norway rat); two are common urban-adapted species (raccoon and striped skunk); and one occurs infrequently in aquatic areas (harbor seal). Of the remaining four species, the Botta's pocket gopher and California vole were represented by no more than one individual on a given survey and thus may be uncommon on the site. These two species, and the California ground squirrel and black-tailed jackrabbit, may decline in abundance on portions of Candlestick Point as extensive weedy/grassland habitats are converted to a mosaic of uses and habitats. However, numbers of these species in open space in HPS Phase II are currently expected to be low due to disturbance from remediation efforts, and enhancement and management of grassland habitat in this area may increase numbers of these species there. Specifically, habitat values on southern HPS Phase II, which has been heavily impacted by remediation efforts, would be enhanced considerably by management of a diverse mosaic of habitats, including native-dominated grasslands and patches of native and site-appropriate trees and shrubs. This area would, therefore, provide new and substantially improved habitat that small mammals can utilize and occupy.

Over time, numbers of some of these small-mammal species may decline due to a reduction in dispersal between patches of suitable grassland habitat and increased urbanization, but all of the terrestrial mammals on the site are regionally abundant and the reduction in their numbers within the site would have a negligible effect on regional populations. The Project would include approximately 105 acres and 232 acres of parkland and open space improvements on Candlestick Point and HPS Phase II, respectively. Although portions of this parkland may serve primarily recreational purposes, parks in the Project area would provide

798 Richer, C. (ed.) 1996. *San Francisco Peninsula Birdwatching*. Sequoia Audubon Society.

an opportunity for planting of vegetation that would provide cover and other resources for use by mammals. The Project would include an 82-acre[799] Grassland Ecology Park that would, at a minimum, contain 43 acres of native-dominated grassland habitat. This grassland would be managed specifically for grassland-associated species, providing enhanced native habitat and foraging opportunities for several mammal species. These new and improved Project components (as implemented through mitigation measure MM BI-7b) would provide new and/or enhanced habitat conditions for small and medium-sized mammals, which would be a beneficial impact.

Fish, Shellfish, and Mollusks

Although no formal fish surveys have been performed, many areas of open water support an array of common estuarine/marine species from encrusting tunicates, sponges, and algae to bottom-dwelling fish (halibut, flounder, and sole), to more open water fish like anchovies, herring, and sardines. Under the worst-case scenario, the Project would affect approximately 29 acres of aquatic habitat, which would have the potential to affect these common species both directly through mortality of individuals or loss of habitat and indirectly through mechanisms such as increased competition, decreased water quality or other common impacts associated with in-water construction. However, the San Francisco Bay is approximately 400 square miles in area, and many of the common species that would be affected by the Project would have ample areas to relocate to. Those individuals that would experience direct mortality represent a very small proportion of the regional populations of these common species. Consequently, the Project's impacts would have a negligible effect on regional populations of common fish and aquatic invertebrates (however, refer to Impact BI-12a and Impact BI-12b below regarding impacts to EFH).

Impact BI-3: Sensitive Plants

Impact of Candlestick Point

Impact BI-3a **Construction at Candlestick Point would not have a substantial adverse effect, either directly or through habitat modifications, on any plant species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (No impact) *[Criteria N.a and N.b]***

Candlestick Point is largely developed. Those areas not developed are highly modified and support only ruderal (disturbed) habitats and ornamental landscaping. Most vegetation in the area has been introduced as landscape plants and turf grass or consists of weedy, non-native species that readily colonize recently disturbed areas. Special-status plants were not observed during any of the focused botanical surveys in 2007 or 2008.[800] Disturbances include: a lack of natural fire regimes (largely since Euro-American settlement); construction of Candlestick Park stadium and associated roads and parking areas; development of CPSRA; increasing competition from invasive non-native species; and on-going disturbances such as vegetation management, trash, and pedestrian traffic. These disturbances have resulted in urbanization of almost all of Candlestick Point. The remaining vegetated areas have been reduced in quality. Because no

[799] This acreage reflects the area of parklands that would be suitable for on-site species and represent only a portion of the total new park lands that would be created by the Project.
[800] Caltrans, Natural Environmental Study Report for the Bayview Transportation Improvements Project, Jones and Stokes, July 2007.

special-status plants have been observed and the site generally does not support the preferred or required soils (i.e., serpentine) needed to support special-status plant species, sensitive plant species are considered absent from Candlestick Point. No impact would occur, and no mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact BI-3b **Construction at HPS Phase II and construction of the Yosemite Slough bridge would not have a substantial adverse effect, either directly or through habitat modifications, on any plant species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (No impact) *[Criteria N.a and N.b]***

HPS Phase II is dominated by industrial and developed areas. The southern shoreline of HPS Phase II and the bridge footprint area is a mixture of salt marsh, seasonal brackish marsh, freshwater seasonal wetland, and non-native annual grassland. Special-status plants were not observed during any of the focused botanical or rare plant surveys in 2007 or 2008.[801] Factors limiting rare plant occurrences within this area include: a lack of natural fire regimes (largely since Euro-American settlement); early maritime development; and construction of a World War II-era Shipyard, as well as post-war development. Those actions have resulted in urbanization of almost all of HPS Phase II. Because no special-status plants have been observed and the site generally does not support the preferred or required soils (i.e., serpentine) needed to support special-status plant species, sensitive plant species are considered absent from HPS Phase II and Yosemite Slough bridge areas. Therefore, no impact would occur, and no mitigation is required.

Impact BI-4: Sensitive Vegetation Communities: Waters of the United States and Navigable Waters

Impact of Candlestick Point

Impact BI-4a **Construction at Candlestick Point would not have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the *Clean Water Act* through direct removal, filling, hydrological interruption, or other means. (Less than Significant with Mitigation) *[Criterion N.c]***

As detailed in Table III.N-4 (Impacts to Wetlands and Other Jurisdictional Waters of the United States [Section 404]) and depicted in Figure III.N-5 (Impacts to Wetlands and Other Waters), through site grading, materials laydown, facilities construction, vegetation removal, and installation of shoreline treatments, Project activities at Candlestick Point would permanently impact 0.29 acre of tidal salt marsh and 4.34 acres of Section 404 "other waters", relative to existing conditions (i.e., prior to completion of remediation efforts by the Navy). Both wetlands and mud flats, the latter comprising a subset of Section 404 "other waters," are considered Special Aquatic Sites under *Clean Water Act* Section 404. It would also temporarily impact 0.01 acre of tidal salt marsh and 0.64 acre of Section 404 "other waters", relative to existing conditions. Permanent impacts are those that would remove wetlands or jurisdictional waters and not replace those habitats in the same location. Temporary impacts are short term because, after construction, any areas disturbed would be restored to the previous condition.

FIGURE III.N-5 ~~Candlestick Point - Hunters Point Shipyard Phase II EIR~>
IMPACTS TO WETLANDS AND OTHER WATERS

Shoreline improvements at Candlestick Point would result in the removal of approximately 2.86 acres of fill, and the placement of approximately 3.46 acres of fill. A net decrease of approximately 0.42 acre of open waters would occur at Candlestick Point. These impacts would occur entirely along the Candlestick Point shoreline as a result of construction of revetments to minimize flooding and shoreline erosion, and as a result of the placement of soils or sand to enhance beach or marsh habitat. For example, along most of the northern and southern edges of Candlestick Point, marsh soils would be placed in jurisdictional areas following completion of the revetment to provide a gentler slope than is currently present, which would allow for colonization by marsh vegetation. As a result, much of the fill of jurisdictional areas (as reflected in Table III.N-4 and Figure III.N-5) would result in an enhancement of habitat and, thus, would be self-mitigating.

In addition to the direct removal of wetlands and other waters, construction in or adjacent to the Bay in the wetlands could also result in indirect impacts such as increased erosion and sedimentation into and hydrologic disruption of wetlands and jurisdictional waters, decreased water quality from construction runoff and potential construction contaminants including oil, grease and fuel, and temporary decrease in habitat functions and values through hydrological disruption or elevated disturbance. However, construction of shoreline revetments would reduce erosion and turbidity in the long term by addressing existing problems with shoreline erosion.

Direct removal, placement of fill into, or hydrological interruption of federally or state-protected wetlands and other waters that would result in a net loss of these areas would be considered a significant impact. However, any alterations of, or discharges into, jurisdictional waters and wetlands must be in conformance with the CWA (via Sections 404 and 401 certification) and Section 10 of the *Rivers and Harbor's Act*, as applicable. These regulations are designed to ensure, among other things, that there is no net loss of wetlands and that water quality is maintained. Additionally, runoff produced during and after construction is subject to National Pollution Discharge Elimination System (NPDES) Regulations and local water quality and runoff standards.

To reduce impacts to wetlands and jurisdictional waters, the following mitigation measures shall be implemented:

MM BI-4a.1 *Wetlands and Jurisdictional/Regulated Waters Mitigation for Temporary and/or Permanent Impacts. Wetlands and jurisdictional waters shall be avoided to the maximum extent practicable for all Project components. For example, any measures taken to improve the existing shoreline of Candlestick Point or HPS Phase II for purposes of flood control, erosion control, or repair or stabilization of existing structures shall minimize the amount of fill to be placed in jurisdictional areas.*

Where avoidance of existing wetlands and drainages is not feasible, and before any construction activities are initiated in jurisdictional areas, the Applicant shall obtain the following permits, as applicable to the activities in question:

- *CWA Section 404 permit from the USACE.*
- *Section 10* Rivers and Harbors Act *Permit from the USACE.*
- *CWA Section 401 water quality certification from the RWQCB, and/or Report of Waste Discharge for Waters of the State.*
- *CWA Section 402/National Pollution Discharge Elimination System permit from SWRCB [requiring preparation of a Stormwater Pollution Prevention Plan (SWPPP)].*

- *CDFG Section 1602 streambed alteration agreement from CDFG.*
- *A permit from the BCDC.*
- *Dredging permits from the USACE and BCDC as required, obtained through the Dredged Material Management Office (DMMO) process.*

Copies of these permits shall be provided to the contractor, along with the construction specifications. The Project Applicant shall be responsible for complying with all of the conditions set forth in these permits, including any financial responsibilities.

Compensation for impacts to wetlands and jurisdictional waters shall be required to mitigate any permanent impacts to these habitats to less-than significant-levels. Such mitigation shall also be developed (separately from the CEQA process) as a part of the permitting process with the USACE, or for non-USACE-jurisdictional wetlands, during permitting through the SFRWQCB, BCDC, and/or CDFG. The exact mitigation ratio shall be established during the permitting process, and depends on a number of factors, including the type and value of the wetlands permanently affected by the Project; however, mitigation shall be provided at a ratio of no less than 1:1 (at least 1 acre of mitigation for every 1 acre of waters of the US/State permanently filled). Mitigation could be achieved through a combination of on-site restoration or creation of wetlands or aquatic habitats (including removal of on-site fill or structures such as piers, resulting in a gain of wetland or aquatic habitats); off-site restoration/creation; and/or mitigation credits purchased at mitigation banks within the San Francisco Bay Region. However, any mitigation for impacts to jurisdictional waters providing habitat for special-status fish such as the green sturgeon, Central California Coast steelhead, Chinook salmon, and longfin smelt must result in the restoration or creation (at a minimum 1:1 ratio) of suitable habitat for these species, and any mitigation for impacts to jurisdictional wetlands or other waters that are considered EFH by the NMFS must result in the restoration or creation (at a minimum 1:1 ratio) of EFH. Suitably planned mitigation sites may satisfy mitigation requirements for jurisdictional areas, special-status fish, and EFH simultaneously (i.e., in the same mitigation areas) if the mitigation satisfies all these needs.

For funding of off-site improvements or purchase of mitigation bank credits, the Project Applicant shall provide written evidence to the City/Agency that either (a) compensation has been established through the purchase of a sufficient number of mitigation credits to satisfy the mitigation acreage requirements of the Project activity, or (b) funds sufficient for the restoration of the mitigation acreage requirements of the Project activity have been paid to the BCDC, CCC, or other entity or agency that offers mitigation credits in the San Francisco Bay Area.

For areas to be restored, to mitigate for temporary or permanent impacts, the Project Applicant shall prepare and implement a Wetland and Jurisdictional Waters Mitigation Monitoring Plan (Mitigation Monitoring Plan). The Plan shall be submitted to the regulatory agencies along with permit application materials for approval, along with a copy to the City/Agency.

The Project Applicant shall retain a restoration ecologist or wetland biologist to develop the Wetland and Jurisdictional Waters Mitigation and Monitoring Plan, and it shall contain the following components (or as otherwise modified by regulatory agency permitting conditions):

1. *Summary of habitat impacts and proposed mitigation ratios, along with a description of any other mitigation strategies used to achieve the overall mitigation ratios, such as funding of off-site improvements and/or purchase of mitigation bank credits*
2. *Goal of the restoration to achieve no net loss of habitat functions and values*
3. *Location of mitigation site(s) and description of existing site conditions*

4. *Mitigation design:*
   - *Existing and proposed site hydrology*
   - *Grading plan if appropriate, including bank stabilization or other site stabilization features*
   - *Soil amendments and other site preparation elements as appropriate*
   - *Planting plan*
   - *Irrigation and maintenance plan*
   - *Remedial measures/adaptive management, etc.*
5. *Monitoring plan (including final and performance criteria, monitoring methods, data analysis, reporting requirements, monitoring schedule, etc.)*
6. *Contingency plan for mitigation elements that do not meet performance or final success criteria.*

Restoration and/or creation of wetlands or aquatic habitats could occur on site or off site and at one or more locations, as approved by the regulatory agencies. Impacts occurring due to activities on Candlestick Point may be mitigated by restoration or creation activities on HPS Phase II and vice versa. For example, loss of open water habitat that might result from construction of shoreline treatments could potentially be mitigated by the removal of fill or structures from aquatic habitat on HPS Phase II.

The Project Applicant, or its agent, shall implement the Wetland and Jurisdictional Waters Mitigation Monitoring Plan. At least five years of monitoring (or more if required as a condition of the permits) shall be conducted to document whether the success criteria (that are determined as part of the mitigation plan) are achieved, and to identify any remedial actions that must be taken if the identified success criteria are not met. Annual monitoring reports (described below) shall be submitted to CDFG, the USACE, the BCDC, the City/Agency, and the SFRWQCB. Each report shall summarize data collected during the monitoring period, describe how the habitats are progressing in terms of the success criteria, and discuss any remedial actions performed. Additional reporting requirements imposed by permit conditions shall be incorporated into the Wetland and Jurisdictional Waters Mitigation Monitoring Plan and implemented.

Success criteria for specified years of monitoring for vegetated mitigation wetlands are as follows (though these may be subject to change pending development of specific Mitigation and Monitoring Plans and consultation during the permit process):

- *Year 1 after restored areas reach elevations suitable for colonization by wetland plants: 10 percent combined area and basal cover (rhizomatous turf) of all vegetation in the preserve wetland; at least two hydrophytic plants co-dominant with whatever other vegetative cover exists.*
- *Year 3 after restored areas reach colonization elevation: 50 percent combined area and basal cover (rhizomatous turf) of all vegetation; prevalence of hydrophytic species in terms of both cover and dominant species composition of the vegetation; native vascular species shall comprise 95 percent of the vegetation in the preserve wetland.*
- *Year 5 after restored areas reach colonization elevation: 70 percent combined area and basal cover (rhizomatous turf) of all vegetation; more than 50 percent dominance in terms of both cover and species composition of facultative (FAC), facultative wetland (FACW), and obligate (OBL) species; native vascular species shall comprise 95 percent of the vegetation in the preserve wetlands.*

Other success criteria shall be developed for open water/mud flat habitats (which would not be expected to support vegetation) or for wetland complexes specifically designed to contain extensive areas of channels, pannes, or flats that would not be vegetated. In addition, the final Project design shall avoid substantial

adverse effects to the pre-Project hydrology, water quality, or water quantity in any wetland that is to be retained on site. This shall be accomplished by avoiding or repairing any disturbance to the hydrologic conditions supporting these wetlands, as verified through an on-site Wetland Protection Plan that shall be prepared by a restoration ecologist or wetland biologist that is retained by the Project Applicant, and submitted to regulatory agencies for approval, along with a copy to the City/Agency. If such indirect effects cannot be avoided, compensatory mitigation shall be provided for the indirectly affected wetlands at a minimum 1:1 ratio, as described above. Mitigation for indirectly impacted wetlands shall be described in the Wetland and Jurisdictional Waters Mitigation and Monitoring Plan.

Project features resulting in impacts to open water areas as a result of the marina, bridge, and breakwater construction shall be designed to be the minimum size required to meet their designated need. The opening in the breakwater shall be large enough and positioned such that it would allow for a complete daily exchange of water within the marina that would otherwise result from normal tidal flow, as determined by a coastal engineer and an aquatic biologist. This opening shall be designed to minimize disruption to the local hydrology generated by the breakwater and allow for normal tidal flow to ensure the daily exchange of nutrients.

MM BI-4a.2 *Wetlands and Jurisdictional/Regulated Waters Impact Minimization for Construction-Related Impacts. The Project Applicant shall ensure that the contractor minimizes indirect construction-related impacts on wetlands and jurisdictional/regulated waters throughout the Study Area by implementing the following Best Management Practices (BMPs):*

- *Prior to any construction activities on the site, a protective fence shall be installed a minimum of one foot (or greater, if feasible) from the edge of all wetland habitat to be avoided in the immediate vicinity of the proposed construction areas. Prior to initiation of construction activities, a qualified biologist shall inspect the protective fencing to ensure that all wetland features have been appropriately protected. No encroachment into fenced areas shall be permitted during construction and the fence shall remain in place until all construction activities within 50 feet of the protected feature have been completed.*
- *Construction inspectors shall routinely inspect protected areas to ensure that protective measures remain in place and effective until all construction activities near the protected resource have been completed. The fencing shall be removed immediately following construction activities.*
- *To maintain hydrologic connections, the Project design shall include culverts for all seasonal and perennial drainages that are waters of the United States and/or Waters of the State.*
- *Sediment mitigation measures shall be in place prior to the onset of Project construction and shall be monitored and maintained until construction activities have been completed. Temporary stockpiling of excavated or imported material shall occur only in approved construction staging areas. Excess excavated soil shall be disposed of at a regional landfill or at another approved and/or properly permitted location. Stockpiles that are to remain on the site throughout the wet season shall be protected to prevent erosion.*
- *Where determined necessary by regulatory agencies, geotextile cushions and other appropriate materials (i.e., timber pads, prefabricated equipment pads, geotextile fabric) shall be used in saturated conditions to minimize damage to the substrate and vegetation.*
- *Exposed slopes and banks shall be stabilized immediately following completion of construction activities to reduce the effects of erosion on the drainage system.*
- *In highly erodible areas, such as Yosemite Slough, banks shall be stabilized using a non-vegetative material that shall bind the soil initially and break down within a few years. If, during review of*

the grading permit for this area, the City/Agency determines that more aggressive erosion control treatments are needed, the contractor shall be directed to use geotextile mats, excelsior blankets, or other soil stabilization products.

- *The contractors shall develop a Storm Water Pollution Prevention Plan (SWPPP) prior to construction. As discussed in the Regulatory Framework of the Hydrology and Water Quality section of this EIR, the SWPPP will comply with applicable local, state, and federal requirements. Erosion control BMPs may include, but are not limited to, the application of straw mulch; seeding with fast growing grasses; construction of berms, silt fences, hay bale dikes, stormwater detention basins, and other energy dissipaters. BMPs shall be selected and implemented to ensure that contaminants are prevented from entering the San Francisco Bay during construction and operation of the facilities shall protect water quality and the marine species in accordance with all regulatory standards and requirements.*
- *Testing and disposal of any dredged sediment shall be conducted as required by the USACE and the Long-Term Management Strategy (LTMS)*[802]
- *All temporarily impacted wetlands and other jurisdictional waters, whether in tidal or non-tidal areas, shall be restored to pre-construction contours following construction. Such impact areas include areas that are dewatered (e.g., using coffer dams) and/or used for construction access. Temporarily impacted wetlands that were vegetated prior to construction shall be revegetated in accordance with a Wetlands and Jurisdictional Water Mitigation and Monitoring Plan as described above.*
- *For impacts to tidal habitats:*
  - *Conduct all work in dewatered work areas*
  - *Install sediment curtains around the worksite to minimize sediment transport*
  - *Work only during periods of slack, tide (minimal current) and low wind to minimize transport of sediment laden water*

Implementation of mitigation measures MM BI-4a.1 and MM BI-4a.2 would reduce the effects of construction-related activities to wetlands by mitigating for the temporary and permanent loss of the wetlands and jurisdictional waters through avoidance of impacts, requiring compensatory mitigation (i.e., creation and/or restoration), obtaining permits from the USACE, SFRWQCB, BCDC, and other agencies as applicable that are designed to protect wetlands and jurisdictional waters, and implementing construction BMPs to reduce and/or prevent impacts to waters of the United States, including wetlands and navigable waters. Consequently, implementation of these mitigation measures would reduce potential adverse effects to wetlands and jurisdictional waters to less-than-significant levels.

[802] US Army Corps of Engineers, US Environmental Protection Agency, San Francisco Bay Conservation and Development Commission, and San Francisco Bay Regional Water Quality Control Board. Long-term Management Strategy for the Placement of Dredge Material in the San Francisco Bay, Management Plan 2001.

Impact of Hunters Point Shipyard Phase II

Impact BI-4b **Construction at HPS Phase II would not have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the *Clean Water Act* (including, but not limited to, marsh, coastal, etc.) through direct removal, filling, hydrological interruption, or other means. (Less than Significant with Mitigation) *[Criterion N.c]***

As detailed in Table III.N-4 and depicted in Figure III.N-5, through site grading, materials laydown, facilities construction, vegetation removal, installation of shoreline treatments, and construction of the marina, Project activities at HPS Phase II would permanently impact existing wetlands and other waters as follows: 0.17 acre of nontidal freshwater wetland, 0.09 acre of tidal salt marsh, 0.15 acre of non-tidal salt marsh, and 20.26 acres of Section 404 other waters. It would also temporarily impact 0.85 acre of Section 404 other waters. Permanent impacts are those that would remove wetlands or jurisdictional waters and not replace them in the same location. Temporary impacts are short term because, after construction, any areas disturbed would be restored to the previous condition.

For the purpose of discussing all project activities that could affect aquatic habitats, impacts to open waters that will result from the removal of existing structures (such as pier headwalls) are considered permanent impacts, since there will be some fill placed within the new open water/intertidal habitat for slope stabilization or restoration purposes after the existing structures are removed. However, such an approach to impact estimation is very conservative, as these activities will result in ecological enhancements by creating new aquatic habitat where none currently exists. As discussed in greater detail below, nearly 10 acres of the total 21.52 acres of impacts to jurisdictional areas on HPS Phase II would result from activities that would enhance ecological conditions along the HPS shoreline.

As mentioned for Candlestick Point above, the impact to tidal salt marsh, Section 404 other waters along the southern shoreline of HPS would occur primarily as a result of the placement of soils along the shoreline to enhance marsh habitat. Following the completion of a revetment by the Navy, the Project Applicant would enhance the revetment as needed (e.g., for aesthetics or to allow it to be more easily raised in the event of sea level rise). However, work to enhance the revetment simply for improved flood control or aesthetics is not expected to result in additional impacts to jurisdictional areas. Rather, the CP/HPS Project would add soil or other materials on the outboard side of the revetment to facilitate the creation of tidal salt marsh in several areas along the southern shoreline of HPS by reducing the revetment's slope and providing a more suitable substrate for colonization by wetland vegetation. As a result, most of the fill of jurisdictional areas (as reflected in Table III.N-4 and Figure III.N-5) along the southern shoreline of HPS (about 1.9 acres of the total acreage impacted at HPS) would result in an enhancement of habitat and, thus, would be self-mitigating.

It is possible that the Yosemite Slough Bridge and its approaches may be constructed before the Navy has completed remediation efforts (including mitigation for its impacts to wetlands) on Parcel E-2. In that case, construction of the bridge and its approaches would impact whatever wetlands have not yet been disturbed, or created, by the Navy, which may include some of the wetlands in the southwestern portion of Parcel E-2 that are included in Table III.N-4 and shown in Figure III.N-5. However, the majority of the non-tidal salt marsh in the southwestern portion of Parcel E-2 would not be impacted by the CP/HPS Project, whether the Navy has completed its remediation efforts or not. If the Navy completes its remediation and construction of its mitigation wetlands before the bridge and its approaches are constructed, then virtually all

of the currently existing wetlands on Parcels E and E-2 (including the approximately 1.8 acres of nontidal wetlands not affected by the Project) would have been impacted by the Navy's work prior to CP/HPS Project construction. A wetland mitigation site, consisting of a tidal and non-tidal component, has been proposed by the Navy on the southwestern corner of Parcel E-2 (refer to Figure III.N-6 [Proposed HPS Phase II Wetlands]). Portions of this proposed mitigation site cannot be avoided during construction of the bridge and its approaches. Thus, if the Navy's mitigation were constructed in the proposed locations, the bridge and roadway right-of-way would permanently impact approximately 0.0992 acre and temporarily impact 0.1532 acre of wetlands on this mitigation site. The remainder of the mitigation site would not be impacted by the CP/HPS Project, but rather would be preserved and incorporated into the Project area.

Of the 21.52 acres of total impacts to jurisdictional wetlands and other waters of the US that would occur on HPS Phase II, jurisdictional areas that would be completely lost (i.e., converted to non-jurisdictional habitats) total only 2.56 acres. This loss of habitat would occur due to construction of the northern abutment of the Yosemite Slough bridge, along the approach road to the bridge, where a freshwater wetland is located in the west-central part of the site, and where construction of new breakwaters, a floating dock, and a gangway would be placed in the marina. Of the remaining impacts, approximately 8.96 acres would result from fill placed for drydock repairs, buttressing required to support existing pier walls and bulkheads, or other shoreline improvements.

The Project also includes the removal of some shoreline structures (i.e., piers and/or bulkheads) and placement or replacement of fill material that are currently present in jurisdictional areas. For example, portions of the Re-gunning pier and edges of bulkheads along much of the eastern part of HPS Phase II would be removed to create new open-water habitat. Although these areas are considered permanently impacted for the purposes of this impact assessment, since some fill would be placed along the new shoreline of these bulkheads for stabilization purposes, removal of structures and fill would restore approximately 8 acres of aquatic habitat. Considering that marsh restoration along the southern edge of HPS is responsible for approximately 1.9 acres of impacts, nearly 10 acres of the total 21.52 acres of impacts to jurisdictional areas on HPS Phase II would result from activities that would enhance ecological conditions along the HPS shoreline.

Direct removal, placement of fill into, or hydrological interruption of federally or state-protected wetlands that would result in a net loss of these areas would be considered a substantial adverse effect. In addition, removal of an established mitigation site would also be considered a substantial adverse effect. However, prior to any grading or construction that may impact jurisdictional area(s), any alterations of, or discharges into, jurisdictional waters and wetlands must be in conformance with the CWA (via Sections 404 and 401 certification) and Section 10 of the *Rivers and Harbors Act*, as applicable. These regulations are designed to ensure, among other things, that there is no net loss of wetlands and that water quality is maintained. Additionally, runoff produced during and after construction is subject to NPDES and local water quality and runoff standards. Lastly, mitigation measures MM BI-4a.1 and MM BI-4a.2 (first discussed in Impact BI-4a) would be implemented to reduce the effects of construction-related activities to wetlands by mitigating for the temporary and permanent loss of the wetlands and jurisdictional waters through avoidance of impacts, requiring compensatory mitigation (i.e., creation and/or restoration), obtaining permits from the USACE, SFRWQCB, BCDC, and other agencies as applicable that are designed to protect wetlands and jurisdictional

PROPOSED HPS PHASE II WETLANDS

waters, and implementing construction BMPs to reduce and/or prevent impacts to on waters of the United States, including wetlands and navigable waters. Consequently, implementation of these mitigation measures would reduce potential adverse effects to less-than-significant levels.

Impact of Yosemite Slough Bridge

Impact BI-4c **Construction of the Yosemite Slough bridge would not have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the *Clean Water Act* (including, but not limited to, marsh, coastal, etc.) through direct removal, filling, hydrological interruption, or other means. (Less than Significant with Mitigation) *[Criterion N.c]***

The new Yosemite Slough bridge would be a nine-span steel-beam bridge as shown on the MACTEC Engineering and Consulting preliminary draft drawings titled "Yosemite Slough Bridge" (Appendix N2).[803] These plans indicate that the bridge would be approximately 81 feet wide and 902 feet long, and would be supported by 20 steel-pile supported columns and 12 bedrock-supported columns.

As detailed in Table III.N-4 and depicted in Figure III.N-5, bridge construction equipment and materials would be staged at the site in designated lay down areas. Construction access and dewatering would result in temporary impacts to 0.52 acre of Section 404 other waters. It would also result in permanent impacts to 0.01 acre of tidal salt marsh, and 0.18 acre of Section 404 other waters.[804] Construction of the piers' pilings would require the excavation of approximately 2,400 cubic yards of material from the slough; 167 cubic yards of material would be excavated from jurisdictional areas for construction of abutments and installation of riprap at the toe of the north and south bridge abutments.[805]

Temporary off-site impacts (i.e., in portions of Yosemite Slough outside the Project boundary) from construction include less than 0.01 acre of tidal salt marsh, and 0.75 acre of Section 404 other waters. Permanent off-site impacts from construction include 0.03 acre of tidal salt marsh and 0.19 acre of Section 404 other waters. In addition to solid material placed within the Bay, the BCDC considers structures suspended above the Bay or floating on the water to be "fill" and subject to their regulation. The "shadow fill" produced by the Yosemite Slough bridge may change the biological functions and values of aquatic and mud flat habitats below to some extent; such an impact would cover approximately 1.48 acres based on the acreage of mudflat below the immediate bridge surface. Shadow fill would not result in the complete loss of functions and values of the aquatic habitats below, however, and many fish and aquatic organisms would continue to use these areas following bridge construction.

Direct removal, placement of fill into, or hydrological interruption of federally or state-protected wetlands that would result in a net loss of these areas would be considered a significant impact. However, any alterations of, or discharges into, jurisdictional waters and wetlands must be in conformance with the CWA (via Sections 404 and 401 certification) and Section 10 of the *Rivers and Harbors Act*, as applicable. These regulations are designed to ensure, among other things, that there is no net loss of wetlands and that water

803 MACTEC. Preliminary Draft: Yosemite Slough Bridge, Sheets 1-7, October 2009, which is provided as Appendix N2 to this EIR.
804 Ibid.
805 Ibid.

quality is maintained. Additionally, runoff produced during and after construction is subject to NPDES and local water quality and runoff standard.

Mitigation measure MM BI-4a.1 shall be implemented to compensate for the loss of wetlands and other jurisdictional waters resulting from the Yosemite Slough bridge. For example, permanent fill of such habitats would be compensated by creation or restoration of jurisdictional habitats on or off site, and/or by the purchase of credits in a mitigation bank; such compensation would be performed in conjunction with compensation for impacts to jurisdictional areas on Candlestick Point and HPS. Any vegetated wetlands that are permanently impacted by shading from the bridge would be mitigated in this manner since shading may inhibit vegetation colonization under the bridge after construction is complete. However, shading of 1.48 acres of mud flats and aquatic habitats would have only moderate effects on the functions and values of these habitats and would not result in the loss of these habitats. Mitigation measure MM BI-4a.2 shall be implemented to minimize indirect construction-related impacts on wetlands and other jurisdictional waters. Further, shading impacts to mud flats and aquatic habitats would be reduced by implementation of mitigation measure MM BI-4c.

MM BI-4c *Mitigation for Shading Impacts to Jurisdictional/Regulated Waters. Mud flats and aquatic habitats impacted by permanent shading from the Yosemite Slough bridge shall be mitigated by the creation or restoration, either on site, off site, and/or via purchase of mitigation bank credits, at a 0.5:1 (mitigation:impacted) ratio. Aside from the mitigation ratio, such mitigation shall be provided as described for mitigation measure MM BI-4a.1.*

Mitigation measures MM BI-4a.1 and MM BI-4a.2 (first discussed in Impact BI-4a) would be implemented to reduce the effects of construction-related activities to wetlands by mitigating for the temporary and permanent loss of the wetlands and jurisdictional waters through avoidance of impacts, requiring compensatory mitigation (i.e., creation and/or restoration), obtaining permits from the USACE, SFRWQCB, BCDC, and other agencies as applicable that are designed to protect wetlands and jurisdictional waters, and implementing construction BMPs to reduce and/or prevent impacts to waters of the United States, including wetlands and navigable waters. In addition, implementation of mitigation measure MM BI-4c would mitigate the impacts of shadow fill to mud flats and aquatic habitats as a result of construction of Yosemite Slough bridge. Consequently, implementation of mitigation measures MM BI-4a.1, MM BI-4a.2, and MM BI-4c would fully mitigate for the temporary and permanent loss of wetlands and jurisdictional waters, and adverse effects would be less than significant.

Impact BI-5: Sensitive Vegetation Communities: Eelgrass Beds

Impact of Candlestick Point

Impact BI-5a **Construction at Candlestick Point would not have a substantial adverse effect on eelgrass beds, a sensitive natural community identified in local or regional plans, policies, and regulations or by the CDFG or USFWS. (No Impact) *[Criterion N.b]***

Development at Candlestick Point would require minor in-water work associated with construction of the shoreline treatments. The distribution of eelgrass has been mapped recently and the results of this effort

indicate that no eelgrass beds are found in the near-shore waters of the Candlestick Point peninsula.[806] Therefore, construction activities at Candlestick Point would have no impact on this sensitive resource. No mitigation is required.

Impact of Hunters Point Shipyard Phase II and Yosemite Slough Bridge

Impact BI-5b **Construction at HPS Phase II and construction of the Yosemite Slough bridge would not have a substantial adverse effect on eelgrass beds, a sensitive natural community identified in local or regional plans, policies, and regulations or by the CDFG or USFWS. (Less than Significant with Mitigation) *[Criterion N.b]***

Within HPS Phase II a total of 1.99 acres of eelgrass has been mapped at two locations (refer to Figure III.N-2). A small eelgrass occurrence was reported along the north shore of the South Basin directly across from Candlestick Point.[807] The only other reported occurrence of eelgrass within HPS Phase II is on the north shore, east of the northern end of Earl Street.[808] This eelgrass bed extends from the end of Earl Street to the pier that forms Drydock 5. These eelgrass beds are mapped as being below mean sea level and, therefore, are spatially separated from areas where shoreline treatments would occur. There are no mapped eelgrass beds where the marina improvements would occur or where the Yosemite Slough bridge would be constructed. However, because the locations of eelgrass occurrence may vary over time, eelgrass not detected during previous surveys could potentially occur in the shallow waters in or near the Yosemite Slough bridge construction footprint, either now or in the future.

The shoreline improvements associated with HPS Phase II include transforming the revetment edge in wave-protected reaches to a more natural looking shoreline by placing suitable fill to cover the revetment that would be constructed by the Navy, which may include Articulated Concrete Block (ACB) mats and/or marsh soils. Shoreline wave berms may be included along the southwest facing shoreline at the bayward end of the ACB mats. If wave berms or other shoreline improvements, or the Yosemite Slough bridge, were constructed in areas where eelgrass beds exist, they could directly impact them through excavation/removal or placement of fill material. Construction of these features or other shoreline treatments near eelgrass beds could also result in the mobilization of some sediment, which, if it were to settle out on eelgrass, could reduce photosynthesis and, therefore, productivity and survival. Because of the ecological importance but regional scarcity of eelgrass beds and the potential contribution of eelgrass beds in the Study Area to populations of aquatic species (and their predators) throughout larger portions of the Bay, any impacts would be considered a substantial reduction in the local population and, therefore, a substantial adverse effect.

To reduce this impact, the following mitigation measures shall be implemented.

MM BI-5b.1 *Avoidance of Impacts to Eelgrass. As the design of shoreline treatments progresses, and a specific Shoreline Treatment Plan is determined, the Plan shall minimize any in-water construction required for installation of any treatment measures near either of the two eelgrass locations noted above.*

[806] San Francisco Bay Eelgrass Inventory, June-October 2003. Prepared for Caltrans and NOAA Fisheries. Prepared by Merkel and Associates, 2003.
[807] Ibid.
[808] Ibid.

MM BI-5b.2 *Eelgrass Survey. Prior to the initiation of construction of the Yosemite Slough bridge or construction of shoreline treatments, an update to the existing eelgrass mapping shall be conducted to determine the precise locations of the eelgrass beds. For the shoreline treatments, this survey shall occur when a final Shoreline Treatment Plan has been prepared. The survey shall be conducted by a biologist(s) familiar with eelgrass identification and ecology and approved by NMFS to conduct such a survey. The area to be surveyed shall encompass the mapped eelgrass beds, plus a buffer of 750 feet around any in-water construction areas on Hunters Point or associated with the Yosemite Slough bridge. Survey methods shall employ either SCUBA or sufficient grab samples to ensure that the bottom was adequately inventoried. The survey shall occur between August and October and collect data on eelgrass distribution, density, and depth of occurrence for the survey areas. The edges of the eelgrass beds shall be mapped. At the conclusion of the survey a report shall be prepared documenting the survey methods, results, and eelgrass distribution within the survey area. This report shall be submitted to NMFS for approval. The survey data shall feed back into the shoreline treatment design process so that Project engineers can redesign the treatments to avoid or minimize any direct impacts to eelgrass beds.*

If the shoreline treatments can be adjusted so that no direct impacts to eelgrass beds would occur, no further mitigation under this measure would be required for shoreline treatment construction. Management of water quality concerns is addressed through mitigation measure MM BI-5b.4 and shall be required to minimize sediment accumulation on the eelgrass. If direct impacts to eelgrass beds cannot be avoided, either by Hunters Point shoreline treatments or Yosemite Slough bridge construction, mitigation measure MM BI-5b.3 shall be implemented.

MM BI-5b.3 *Compensatory Eelgrass Mitigation. If direct impacts to eelgrass beds cannot be avoided, compensatory mitigation shall be provided in conformance with the Southern California Eelgrass Mitigation Policy. Mitigation shall entail the replacement of impacted eelgrass at a 3:1 (mitigation:impact) ratio on an acreage basis, based on the eelgrass mapping described in mitigation measure MM BI-5b.2 and detailed designs of the feature(s) that would impact eelgrass beds. Such mitigation could occur either off site or on site.[809] Off-site mitigation could be achieved through distribution of a sufficient amount of funding to allow restoration or enhancement of eelgrass beds at another location in the Bay. If this option is selected, all funds shall be distributed to the appropriate state or federal agency or restoration-focused non-governmental agency (i.e., CDFG restoration fund, California Coastal Conservancy, Save the Bay, etc). The Project Applicant shall provide written evidence to the City/Agency that either a) compensation has been established through the purchase of a sufficient number of mitigation credits to satisfy the mitigation acreage requirements of the Project activity, or b) funds sufficient for the restoration of the mitigation acreage requirements of the Project activity have been paid. These funds shall be applied only to eelgrass restoration within the Bay.*

If on-site mitigation is selected as the appropriate option, the Project Applicant shall retain a qualified biologist familiar with eelgrass ecology (as approved by the City/Agency) to prepare and implement a detailed Eelgrass Mitigation Plan. Unless otherwise directed by NMFS, the Eelgrass Mitigation Plan shall follow the basic outline and contain all the components required of the Southern California Eelgrass Mitigation Policy (as revised in 2005),[810] including: identification of the mitigation need, site, transplant methodology, mitigation extent (typically 3:1 on an acreage basis[811]), monitoring protocols (including

[809] NMFS, Southwest Regional Office, Southern California Eelgrass Mitigation Policy, as revised August 30, 2005. Website: http://swr.nmfs.noaa.gov/hcd/policies/EELPOLrev11_final.pdf. Accessed July 20, 2009.
[810] NMFS, Southwest Regional Office, Southern California Eelgrass Mitigation Policy, as revised August 30, 2005. Website: http://swr.nmfs.noaa.gov/hcd/policies/EELPOLrev11_final.pdf. Accessed July 20, 2009.
[811] US Army Corps of Engineers, US Environmental Protection Agency, San Francisco Bay Conservation and Development Commission, and San Francisco Bay Regional Water Quality Control Board. Long-term Management

frequency, staffing, reviewing agencies, duration, etc), and success criteria. A draft Eelgrass Mitigation Plan shall be submitted to NMFS, for its review and approval prior to implementation, with a copy to the City/Agency. Once the plan has been approved, it shall be implemented in the following appropriate season for transplantation. Restored eelgrass beds shall be monitored for success over a 5-year period.

MM BI-5b.4 *Eelgrass Water Quality BMPs. To prevent sediment that could be suspended during construction from settling out onto eelgrass, for any shoreline treatments within 750 feet of identified eelgrass beds, the Project Applicant shall require the selected contractor to implement appropriate BMPs that could include any or all of the following options, or others deemed appropriate by NMFS:*

1. *Conduct all work in dewatered work areas*
2. *Conduct all in-water work during periods of eelgrass dormancy (November 1-March 31)*
3. *Install sediment curtains around the worksite to minimize sediment transport*
4. *Work only during periods of slack tide (minimal current) and low wind to minimize transport of sediment laden water*

Implementation of mitigation measures MM BI-5b.1 through MM BI-5b.4 would reduce the effects of shoreline treatments on eelgrass by avoiding impacts through initial design if feasible; determining the locations of eelgrass beds through surveys; using survey data to refine shoreline treatments to further avoid or minimize impacts to eelgrass; and compensating for unavoidable impacts through the creation or restoration of eelgrass beds at a 3:1 ratio, thus replacing impacted habitat and increasing its abundance regionally. Consequently, implementation of these mitigation measures would reduce potential adverse effects to less-than-significant levels.

Impact BI-6: Birds

Impact of Candlestick Point

Impact BI-6a **Construction at Candlestick Point would not have a substantial adverse effect, either directly or through habitat modifications, on any bird species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (Less than Significant with Mitigation) *[Criterion N.a]***

Special-status avian species (as defined in the Setting portion of this section) for which suitable habitat is present on site, and that have a "low" or better potential to occur, include the Alameda song sparrow, American peregrine falcon, burrowing owl, Bryant's savannah sparrow, California brown pelican, loggerhead shrike, northern harrier, San Francisco common yellowthroat, short-eared owl, tricolored blackbird, and white-tailed kite (refer to Table III.N-5). Some of these species have never nested on the Project site and are not expected to nest here due to the absence of suitable nesting habitat, human disturbance, or predation risk; such species include the California brown pelican, northern harrier, short-eared owl, and tricolored blackbird. Of the remaining species, only the American peregrine falcon has been confirmed breeding on the site; operational impacts to this species are discussed in Impact BI-16 below. For reasons described previously, there is a low probability that the Alameda song sparrow, burrowing owl, Bryant's savannah sparrow, loggerhead shrike, San Francisco common yellowthroat, and white-tailed kite

Strategy for the Placement of Dredge Material in the San Francisco Bay, Management Plan 2001; Appendix F – ESA and EFH Consultation.

currently breed here. Nevertheless, if any of these special-status species nests on the site, there is some potential that active nests, including eggs or young, could be destroyed by vegetation removal, grading, or other Project activities, or that Project activities could disturb nesting adults to the point of nest abandonment, causing the loss of eggs or young.

In addition to recognized special-status species, as discussed above in Regulatory Framework, all native bird species that may use the site are protected under the MBTA and *California Fish and Game Code*. These laws protect many common species in addition to those considered special-status species.

It is unlikely that construction activities would result in the loss of free-flying birds (though see Impact BI-20a for a discussion of potential bird-strike issues associated with bright lights or tall buildings). However, Project implementation and construction-related activities including, but not limited to, grading, materials laydown, facilities construction, vegetation removal, and construction vehicle traffic may result in loss of a special-status and/or legally protected avian species' active nest and/or mortality of the nest's occupants. Due to the relatively low regional populations of any special-status species that might nest on the site, the loss of active nests of a special-status bird would be significant. Although most other, non-special-status birds that may nest on the site are more common regionally, and the Project would provide a net benefit to many protected bird species, including breeding, migrant, and wintering birds, as a result of habitat enhancements, impacts to active nests of any native bird would be considered significant due to these species' protection by the MBTA and *California Fish and Game Code*.

To reduce these impacts the following mitigation measures would be implemented:

MM BI-6a.1 *Impact Avoidance and Pre-Construction Surveys for Nesting Special-Status and Legally Protected Avian Species. The following measures shall be implemented by the Project Applicant to avoid impacts to nesting birds.*

1. *Not more than 15 days prior to construction activities that occur between February 1 and August 31, surveys for nesting birds shall be conducted by a qualified biologist (one familiar with the breeding biology and nesting habits of birds that may breed in the Project vicinity) that is selected by the Project Applicant, and approved by the City/Agency. Surveys shall cover the entire area to be affected by construction and the area within a 250-foot buffer of construction or ground-disturbing activities. The results of the surveys, including survey dates, times, methods, species observed, and a map of any discovered nests, shall be submitted to the City/Agency. If no active avian nests (i.e. nests with eggs or young) are identified on or within 250 feet of the limits of the disturbance area, no further mitigation is necessary. Phased construction work shall require additional surveys if vegetation or building removal has not occurred within 15 days of the initial survey or is planned for an area that was not previously surveyed. Alternatively, to avoid impacts, the Project Applicant shall begin construction after the previous breeding season for local raptors and other special-status species has ended (after August 31) and before the next breeding season begins (before February 1).*
2. *If active nests (with eggs or young) of special-status or protected avian species are found within 250 feet of the proposed disturbance area, a minimum 250-foot no-disturbance buffer zone surrounding active raptor nests and a minimum 100-foot buffer zone surrounding nests of other special-status or protected avian species shall be established until the young have fledged. Project activities shall not occur within the buffer as long as the nest is active. The size of the buffer area may be reduced if a qualified biologist familiar with the species' nesting biology (as approved by the City/Agency) and CDFG determine it would not be likely to have adverse effects on the particular species.*

Alternatively, certain activities may occur within the aforementioned buffers, with CDFG concurrence, if a qualified biologist monitors the activity of nesting birds for signs of agitation while those activities are being performed. If the birds show signs of agitation suggesting that they could abandon the nest, activities would cease within the buffer area. No action other than avoidance shall be taken without CDFG consultation.

3. *Completion of the nesting cycle (to determine when construction near the nest can commence) shall be determined by a qualified biologist experienced in identification and biology of the specific special-status or protected species.*

MM BI-6a.2 *Burrowing Owl Protocol Surveys and Mitigation. Because burrowing owls may take refuge in burrows any time of year, species-specific measures are necessary to avoid take of this species. The following measures shall be undertaken by the Project Applicant to protect burrowing owls.*

Prior to construction activities, focused pre-construction surveys shall be conducted for burrowing owls where suitable habitat is present within the construction areas. Surveys shall be conducted by a qualified biologist (i.e., one who is familiar with burrowing owl ecology and experienced in performing surveys for them, as approved by the City/Agency) no more than 30 days prior to commencement of construction activities. These surveys shall be conducted in accordance with the burrowing owl survey protocol contained within California Burrowing Owl Consortium's April 1995 Burrowing Owl Survey Protocol and Mitigation Guidelines, or any more current equivalent should new guidelines be released before construction.

1. *If no occupied burrows are found in the survey area, a letter report documenting survey methods and findings shall be submitted to the City/Agency and CDFG, and no further mitigation is necessary.*
2. *If unoccupied burrows are found during the non-breeding season, prior to construction activities, the Project Applicant shall collapse the unoccupied burrows, or otherwise obstruct their entrances to prevent owls from entering and nesting in the burrows. This measure would prevent inadvertent impacts during construction activities.*
3. *If occupied burrows are found, a letter report documenting survey methods and findings (including a map showing the locations of the occupied burrows) shall be submitted to the City/Agency and CDFG. Impacts to the burrows shall be avoided by providing a construction-free buffer of 250 feet during the nesting season (February 1 through August 31). A buffer of 165 feet from the active burrows should be provided during the non-breeding season (September 1 through January 31) if feasible, though a reduced buffer is acceptable during the non-breeding season as long as construction avoids direct impacts to the burrow(s) used by the owls. The size of the buffer area may be reduced if the CDFG determines it would not be likely to have adverse effects on the owls. No Project activity shall commence within the buffer area until a qualified biologist (as approved by the City/Agency) confirms that the burrow is no longer occupied. If the burrow is occupied by a nesting pair, as recommended by the California Burrowing Owl Consortium's April 1995* Burrowing Owl Survey Protocol and Mitigation Guidelines*, a minimum of 6.5 acres of foraging habitat contiguous (immediately adjacent) to the burrow shall be maintained until the nesting season is over. If the foraging habitat contiguous to the occupied burrow is currently less than 6.5 acres, the entire foraging habitat shall be maintained until the nesting season is over.*
4. *If impacts to occupied burrows are unavoidable, passive relocation techniques approved by CDFG shall be used to evict owls from burrows within the construction area prior to construction activities. However, no occupied burrows shall be disturbed during the nesting season unless a qualified biologist (as approved by the City/Agency) verifies through non-invasive methods that juveniles from the occupied burrows are foraging independently and are capable of independent survival, or verifies the owls have not yet laid eggs. If any breeding owls must be relocated (i.e., after the nesting*

season has ended), mitigation of impacts to lost foraging and nesting habitat for relocated pairs shall follow guidelines provided in the California Burrowing Owl Consortium's April 1995 Burrowing Owl Survey Protocol and Mitigation Guidelines, which depending upon conditions detailed in the guidance (such as mitigation habitat quality), range from 7.5 to 19.5 acres per pair. This mitigation may take the form of the purchase of credits in a burrowing owl mitigation bank or the preservation and management of the required habitat acreage on site (e.g., in the Grasslands Ecology Park) or off site. If mitigation is provided via on-site or off-site habitat preservation and management, a Burrowing Owl Habitat Management Plan shall be prepared by a qualified biologist and submitted to the CDFG for review and approval, along with a copy to the City/Agency. This plan shall detail the location of the mitigation site, the means of preservation of the site (i.e., via a conservation easement), any enhancement and management measures necessary to ensure that habitat for burrowing owls is maintained in the long term, a monitoring program, and the size of an endowment established for the long-term maintenance of the site.

Implementation of mitigation measures MM BI-6a.1 and MM BI-6a.2 would reduce the effects of Project construction and implementation on nesting special-status and legally protected avian species by surveying for, identifying, and avoiding occupied nests and delaying construction if necessary to prevent nest abandonment, and/or providing a buffer zone around occupied nests to ensure that disturbance from construction activities do not result in the loss of individuals or destruction of nests or eggs. In addition, mitigation measure MM BI-6a.2 would require focused surveys for burrowing owls and specifies active and passive impact avoidance measures to avoid impacting this species and replace lost habitat. Specifically, if these species are identified nesting within the site, mitigation measures would implement construction buffers to protect occupied burrows, eggs, and young, as dictated by site-specific conditions in consultation with CDFG. Implementation of these mitigation measures would reduce potential adverse effects to less-than-significant levels by avoiding the loss of special-status or legally protected nesting species.

Impact of Hunters Point Shipyard Phase II

Impact BI-6b **Construction at HPS Phase II would not have a substantial adverse effect, either directly or through habitat modifications, on any bird species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (Less than Significant with Mitigation) *[Criterion N.a]***

Similar to development at Candlestick Point, construction-related activities including, but not limited to, grading, materials laydown, facilities construction, vegetation removal, and construction vehicle traffic may result in loss of a special-status and/or legally protected avian species' active nest and/or mortality of the nest's occupants; this would be considered a significant impact. Implementation of mitigation measures MM BI-6a.1 and MM BI-6a.2 (as detailed in Impact BI-6a), both at HPS Phase II and Yosemite Slough, would reduce the effects of Project construction and implementation on nesting special-status and legally protected avian species to less-than-significant levels.

A resident pair of American peregrine falcons has been observed successfully nesting on the Re-gunning crane on Parcel D of HPS Phase II. The Project would not remove the Re-gunning crane on Parcel D and, therefore, would not remove the nesting site. However, construction-related activities such as noise and light generating activities may disturb peregrine nesting activities. Peregrines are a state-listed endangered species (though the California Fish and Game Commission recently voted for delisting) and fully protected

under the *California Fish and Game Code*. If Project-generated disturbance is high enough, this pair of falcons could abandon the nest site entirely; due to the relatively low regional populations of this species, the loss of eggs or young due to abandonment of an active nest would be considered a substantial adverse effect and a significant impact. However, researchers at the Santa Cruz Predatory Bird Research Group[812,813] who were contacted about this Project's potential impact to this species expressed their professional opinion that like many other raptors, these peregrine falcons are expected to continue normal nesting activities if the nest site is left alone. Mitigation measure MM BI-6b would ensure effects of Project construction to nesting peregrine falcons are reduced to a less-than-significant level by identifying active nests during pre-construction surveys, delaying construction (if necessary) to limit disturbance.

MM BI-6b *American Peregrine Falcon Nest Protection Measures. To protect the nest of peregrine falcons during construction, the following measures shall be implemented by the Project Applicant prior to construction or other disturbance within 500 feet of the Re-gunning crane nest.*

1. *Not more than 30 days prior to construction activities that occur between February 1 and August 15, surveys for nesting peregrine falcons shall be conducted on the Re-gunning crane, and within a 500-foot buffer surrounding the potential nesting location. Surveys shall be performed by a qualified biologist (i.e., one familiar with falcon biology and nesting) that is selected by the Project Applicant, and approved by the City. The results of the surveys shall be submitted to the City/Agency and the CDFG. If no active peregrine falcon nests, eggs, or breeding activity, are identified on or within 500 feet of the limits of the disturbance area, no further mitigation is necessary. Alternatively, to avoid impacts, the Project Applicant can begin construction after the previous breeding season has ended (after August 31) and before the next breeding season begins (before February 1).*
2. *If active peregrine nests or breeding activity are observed within the survey area, a minimum 250-foot no disturbance buffer zone surrounding the nesting location shall be established until the young have fledged. Within this buffer, no Project construction activities shall occur while the nest is active. The size of the buffer area may be reduced if a qualified biologist and CDFG determine it would not be likely to have adverse effects on the falcons. No action other than avoidance shall be taken without CDFG consultation.*
3. *No new Project construction activity shall commence within the buffer area until young have fledged and the nest is no longer active, or until nesting has been terminated for reasons unrelated to Project activities. Completion of the nesting cycle shall be determined by a qualified biologist who is experienced in peregrine falcon breeding biology (as determined by the City/Agency).*

Implementation of mitigation measures MM BI-6a.1, MM BI-6a.2, and MM BI-6b would reduce the effects of Project construction and implementation on nesting special-status and legally protected avian species to less-than-significant levels.

[812] Glenn Stewart, Coordinator, UCSC Predatory Bird Research Group. E-mail correspondence July 13, 2009.
[813] The Santa Cruz Predatory Bird Research Group was founded to help restore a peregrine falcon population that had plummeted to just two known breeding pairs in California. SCPBRG conducts research to monitor and develop innovative management techniques and strategies to accelerate the recovery of peregrine falcon populations and other predatory birds.

Impact BI-7: Foraging Habitat for Raptors

Impact of Candlestick Point

Impact BI-7a **Construction at Candlestick Point would not have a substantial adverse effect on the quantity and quality of suitable foraging habitat for raptors. (Less than Significant) *[Criterion N.a]***

Construction on Candlestick Point would remove approximately 5.13 acres of non-native grasslands within Candlestick Point that serve as foraging habitat for grassland-associated raptors such as the red-tailed hawk (*Buteo jamaicensis*) and American kestrel (*Falco sparverius*). Maximum counts (per survey) of eight red-tailed hawks and two American kestrels were recorded during the Yosemite Slough Watershed Wildlife surveys. Alteration of grassland habitat would also cause local reductions in habitat for prey of these raptors as well, in the areas being converted from grassland to developed uses. However, the majority of construction activities associated with Candlestick Point would not occur within grasslands and associated suitable raptor foraging habitat; rather, most of the Study Area's existing grasslands occur in areas that would not be transferred from CPSRA parkland and would, therefore, not be affected by Project activities. Therefore, adverse effects of development at Candlestick Point on raptor foraging habitat would be less than significant. No mitigation is required.

In addition, the Project's proposed ecological enhancements (as detailed in Impact BI-2), which would be refined in the Project's Draft Parks, Open Space, and Habitat Concept Plan, include measures to restore and manage areas that would be highly suitable as raptor foraging habitat. These measures would be required by MM BI-7b if this mitigation measure is adopted. The Project's enhancement of non-native grasslands that would be suitable replacement foraging habitat would, overall, be beneficial to grassland-associated raptors and more than offset any adverse effects from the removal of non-native grasslands at Candlestick Point.

Impact of Hunters Point Shipyard Phase II

Impact BI-7b **Implementation of the Project at HPS Phase II would not have a substantial adverse effect on the quantity and quality of suitable foraging habitat for raptors. (Less than Significant with Mitigation) *[Criterion N.a]***

Project activities associated with HPS Phase II would involve the creation of a Grasslands Ecology Park on the southern portion of HPS. Landscaping associated with creation of this park would alter approximately 43 acres of non-native grasslands within the HPS Phase II that currently serve as raptor foraging areas. As historic raptor foraging areas within the City have been reduced due to the conversion of open space to urbanized environments, permanent loss of suitable foraging habitat would be considered a substantial adverse effect.

However, the Project's proposed ecological enhancements (as detailed in Impact BI-2), which would be refined in the Project's Draft Parks, Open Space, and Habitat Concept Plan, include measures to restore and manage areas that would be highly suitable as raptor foraging habitat. Specifically, the Project's impacts to 43 acres of non-native grasslands that currently serve as raptor foraging habitat would occur as a result of enhancements that would be made to create a variety of habitats, including extensive grasslands, within the Grasslands Ecology Park. At least 43 acres of the Grasslands Ecology Park would be enhanced by

removal of invasive plants and restoration of native-dominated grasslands, and this area would be managed specifically for grassland-associated species. As a result, it would provide enhanced foraging opportunities for raptors and enhanced habitat for their prey when compared to the unmanaged, heavily disturbed non-native grasslands that currently occupy most portions of the HPS Phase II that are not already developed. Management of grasslands for grassland-associated prey species such as small mammals would benefit raptors such as American kestrels, red-tailed hawks, and barn owls that frequently forage in grasslands. Throughout the Project site, including parks and open space areas on both Candlestick Point and HPS Phase II, approximately 10,000 net new trees (more than four times the number currently present in the Project area) would be planted at the Project site and in the community. Many of these trees would be suitable for raptor perching, some of which would provide raptor nest sites as they mature. As discussed previously, the Project's planting of trees and shrubs would increase the abundance of smaller birds on the site, and increases in the general abundance of migratory birds as a result of shrub and tree planting would increase prey for raptors such as Cooper's hawks, sharp-shinned hawks, and merlins that specialize on birds, thus enhancing the quality of foraging habitat for these raptors. Because habitat use by red-shouldered hawks (*Buteo lineatus*) can be limited by perch availability in vast open areas, the introduction of perches by planting of trees near grasslands is expected to enhance foraging habitat conditions on large open areas such as southern HPS Phase II, as has been documented in southern California.[814]

The Project's Draft Parks, Open Space, and Habitat Concept Plan would identify ecological enhancement measures that would include the restoration and management of suitable raptor foraging habitat. To provide a mechanism by which implementation of these enhancements would be ensured, mitigation measure MM BI-7b shall be implemented to ensure that specific standards related to the enhancement of raptor foraging habitat would occur.

MM BI-7b *Enhancement of Raptor Foraging Habitat. The Draft Parks, Open Space, and Habitat Concept Plan shall implement, at a minimum, the following measures in open space areas outside the CPSRA, and if allowed, within the CPSRA area:*

- ***Restoration and Management of Grasslands:*** *To maintain grassland-associated wildlife species on the site, grasslands extensive enough to support such species shall be maintained and enhanced through the restoration of native grasses. Such grassland habitat shall not be well manicured or regularly mown. No trees shall be planted within such areas, and shrub cover would be limited to a few small, scattered patches of low-statured coastal scrub plants. At a minimum, replacement of non-native grassland impacted at HPS Phase II with native-dominated grassland shall occur at a ratio of 1:1 (1 acre of native-dominated grassland restored: 1 acre of non-native grassland impacted).*
- ***Increase in Tree/Shrub Cover:*** *Trees and shrubs (particularly natives) shall be planted and maintained outside the designated grassland restoration area to provide foraging habitat for raptors and other migratory birds, and cover for mammals, reptiles, and smaller birds that may serve as raptor prey. While native vegetation shall be favored, site-appropriate non-native trees and shrubs that provide food or structural resources that are particularly valuable to native wildlife shall also be considered. Approximately 10,000 net new trees shall be planted at the Project site and in the community, in addition to trees that will be replaced as required by the Urban Forestry Ordinance or MM BI-14a.*

[814]Bloom, P. H. and M. D. McCrary. 1996. The urban Buteo: red-shouldered hawks in southern California. Pages 31-39 in D. Bird, D. Varland, and J. Negro (eds.), Raptors in Human Landscapes. Academic Press.

The elements identified above shall be reviewed and approved by a qualified biologist (one familiar with the ecology of the Project site), and the Draft Parks, Open Space, and Habitat Concept Plan shall be implemented during construction of the Project. This plan shall be approved by the Agency prior to construction, and its preparation and implementation shall be the financial responsibility of the Project Applicant.

The Project's ecological enhancements (as detailed in the Draft Parks, Open Space, and Habitat Concept Plan), the requirements specified in mitigation measure MM BI-7b, and new and improved parkland, would provide both raptor foraging opportunities and enhanced raptor and raptor prey habitat. Consequently, adverse effects to raptor foraging habitat would be less than significant. Further, these Project improvements would result in a net increase in the quality of suitable raptor foraging habitat, as well as providing ancillary habitat improvement benefits to their prey species (small mammals, birds, and insects) that could result in a higher prey base for raptors within HPS Phase II. Overall, with mitigation, the effect of the Project on raptors is expected to be beneficial.

Impact BI-8: Terrestrial Mammals: Western Red Bat

Impact of Candlestick Point

Impact BI-8a **Construction at Candlestick Point would not have a substantial adverse effect, either directly or through habitat modifications, on the western red bat, a species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (Less than Significant) *[Criterion N.a]***

The only special-status bat species with the potential to occur within the Study Area is the western red bat. Potential roosting habitat for this species is present within the Project site in the mature trees where bats would roost in the foliage during migration and during the winter months (August–April). Construction activities that would remove these potential roosting sites could result in a small number of individuals being displaced, injured, or killed. However, several factors need to be taken into account when assessing the potential significance of the displacement or potential loss of a limited number of these individuals:[815]

1. This species is not a communal rooster, and any one tree would not be expected to contain large numbers of this species. Thus, any impacts to individuals would be very limited on a per-tree basis.
2. This species is highly affiliated with riparian communities that are dominated by mature trees with stands that are greater than 50 meters wide (i.e., red bat populations require fairly extensive stands of riparian forest). Consequently, the habitat on site is not of high quality for roosting or foraging and not essential to the species' survival or reproduction. As a result, few individuals are likely to be present on the site at any one time, and the number of individuals that could be directly impacted by the Project would be very low.
3. This species is not known to breed along the coast and is thought to migrate out of coastal regions to breed. Thus, the habitat on site would not be used for breeding and young would not be impacted.
4. Individuals roost in the canopy, generally well above any work areas and are averse to human disturbances and noise. Thus, if individuals were present they would not be directly impacted by tree

[815] Pierson, E.D., W.E. Rainey and C. Corben. 2006. Distribution and status of western red bats (*Lasiurus blossevillii*) in California. Calif. Dept. Fish and Game, Habitat Conservation Planning Branch, Species Conservation and Recovery Program Report 2006-04, Sacramento, CA 45 pp.

removal machinery as they are highly sensitive to noise and disturbance and would likely disperse to other areas while the trees are being removed.

5. The Central Valley of California, particularly the Sacramento and San Joaquin drainages and the lower reaches of the large rivers that drain the Sierra Nevada (i.e., Tuolumne, Merced, and likely the American and Cosumnes), take on disproportional importance for the future viability of this species. Thus, from an ecological sense, the Project would not impact critical range of this species or individuals occupying those areas.

Consequently, while removal of large trees could lead to disturbance and mortality of a very limited number of this species, the loss or disturbance would not represent a substantial adverse effect as it would not substantially reduce the habitat of this species, cause its population to drop below self-sustaining levels, or reduce its range. Impacts would be less than significant, and no mitigation is required.

In addition, the Project's Draft Parks, Open Space, and Habitat Concept Plan identifies ecological enhancement measures, including the planting of approximately 10,000 net new trees at the Project site and in the community, many of which would be suitable roosting habitat for this species, and result in an increase in potential roosting sites. These measures would be required by MM BI-7b. In addition, mitigation measure MM BI-14a requires the replacement of removed trees at a 1:1 ratio. With implementation of MM BI-7b and MM BI-14a, the effect of construction activities at Candlestick Point on the western red bat would be expected to be beneficial.

Impact of Hunters Point Shipyard Phase II

Impact BI-8b **Construction at HPS Phase II would not have a substantial adverse effect, either directly or through habitat modifications, on the western red bat, a species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (Less than Significant) *[Criterion N.a]***

Similar to development at Candlestick Point, potential roosting habitat for this species is present within the Project site in the mature trees where bats would roost in the foliage during migration and the winter months (August—April). Construction activities that would remove these potential roosting sites could result in a small number of individual being displaced, injured, or killed. However, as detailed in Impact BI-8a, while removal of large trees could lead to disturbance and mortality of a very limited number of this species, the loss or disturbance would not represent a substantial adverse effect as it would not substantially reduce the habitat of this species, cause its population to drop below self-sustaining levels, or reduce its range. Impacts would be less than significant, and no mitigation is required. Further, as discussed in Impact BI-8a, with implementation of MM BI-7b and MM BI-14a, the effect of construction activities on the western red bat would be expected to be beneficial.

Impact BI-9: Marine Mammals and Fish

Impact of Candlestick Point

Impact BI-9a **Pile driving associated with construction at Candlestick Point would not have a substantial adverse effect either directly or through habitat modifications, on marine mammals or fish identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (No Impact) *[Criterion N.a]***

Development in Candlestick Point has no in-water components that require pile driving and, therefore, would have no substantial adverse effects to sensitive fish or marine mammals as a result of pile driving. No impact would occur, and no mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact BI-9b **Pile driving associated with construction of the marina and the Yosemite Slough bridge would not have a substantial adverse effect at HPS Phase II, either directly or through habitat modifications, on marine mammals or fish identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (Less than Significant with Mitigation) *[Criterion N.a]***

It is possible that any of the sensitive fish species listed in the Setting section could be found within aquatic habitats of HPS Phase II during certain times of year. Those include green sturgeon, Chinook salmon, steelhead, and longfin smelt. Marine mammals such as the harbor seal and California sea lion could also be present. Pacific herring and a number of other non-special-status fish could also occur in these waters. The high noise levels generated by pile driving have the potential to disturb, injure, or kill these species.

Construction of the marina would require the use of a pile driver to install the new pilings required to anchor the floats. New piles may also need to be driven to support and stabilize existing wharves if future investigations identify weaknesses in existing support structures. When piles are struck by a hammer, they generate ground vibrations and sound. When this occurs in the air, we hear the result. When this occurs in water, the effect is transmitted as a pressure wave. The magnitude of this wave is dependent on the type of pile being installed (solid, hollow, concrete, wood, steel) and the hammer being used (impact or vibratory). The combination that generates the strongest wave is a hollow steel pile struck with an impact hammer.

The in-water pressure wave, if of sufficient magnitude, can injure or kill fish. Pressure waves have an actual force associated with them and the stronger the force, the more likely they are to damage sensitive tissues in fish. Pressure waves interact with fish in the water column generating effects from behavioral such as avoidance, to physiological such as stress, temporary loss of hearing, rupture of swim bladders (air pockets that are used for buoyancy), formation of bubbles in the circulatory system and corresponding rupturing of blood vessels, traumatic brain injuries, to death.[816] Species with swim bladders are the most susceptible although ear structures of any species can be damaged. Current NMFS guidelines indicate that 180 decibels generating 1 micropascal

[816] Hasting, M.C. and A.N. Popper. Effects of sound on fish. Prepared for California Department of Transportation, January 28, 2005.

can injure or kill fish.[817,818] Marine mammals, which have sensitive hearing, can easily be disturbed by sound-generated pressure waves although it would be unlikely to cause injury or mortality.

Construction of the marina could require the installation of about 675 new pilings.[819] The conceptual design of the marina does not specify pile installation methods, type of pile, or the season during which installation could occur. Based on experience with other marina improvements in San Francisco Bay, steel piles are likely required for at least some structural elements of the marina. As was discussed above, installation of these piles with an impact hammer has the potential to generate substantial sound pressure waves. Installation of pilings that resulted in generation of sound pressure waves above the threshold indicated could result in the mortality of any of the sensitive species of fish listed above. Additionally, the noise would disrupt normal behavior patterns of marine mammals, which would be a violation of the *Marine Mammal Protection Act*. Either of these effects would be considered a potentially significant impact.

The current design for the Yosemite Slough bridge would have 20 columns supported by steel piles. However, current Yosemite Slough bridge designs would require installation of coffer dams (temporary structures typically constructed with sheet-pilings[820] that separate a worksite from the water and allow it to be dewatered). The bridge piles would be driven behind dewatered coffer dams. Because piles would be driven behind the coffer dam and, therefore, out of the water, pile installation would not result in generation of in-water sound pressure waves that could injure fish species, and ground pressure waves produced by pile driving within a dewatered coffer dam are not expected to injure fish.

To reduce these impacts the following mitigation measures would be implemented:

MM BI-9b *Pile Driving Design and Minimization Measures. To minimize impacts on fish and marine mammals, the Project Applicant shall implement the following measure to reduce the amount of pressure waves generated by pile driving. The first set of measures shall be implemented during Project design. The second set of measures shall be implemented during construction.*

Design Measures:

1. *Engineer structures to use fewer or smaller piles, where feasible, and preferably, solid piles.*
2. *Design structures that can be installed in a short period of time (i.e., during periods of slack tide when fish movements are lower).*
3. *Do not use unsheathed creosote-soaked wood pilings.*

The City/Agency, with consultation from a qualified biologist who is familiar with marine biology, as approved by the City/Agency, shall review the final Project design to ensure that these design requirements have been incorporated into the Project.

Construction Measures:

1. *Drive piles with a vibratory device instead of an impact hammer if feasible.*

[817] A micropascal is a measure of pressure per unit area where 1 micropascal equals 0.0000145 pounds per square inch.
[818] NMFS. San Francisco Bay Project Impact Evaluation System. Website: http://mapping2.orr.noaa.gov/website/portal/pies/piledriving.html. Accessed February 16, 2009.
[819] Devick, C. Moffat & Nichol. E-mail to C. Mason and D. Ebert, January 15, 2009 with fill volumes for the Marina.
[820] Sheet piles are flat metal "boards" that are driven into the substrate with a pile driver. They interlock with each other to form a vertical water tight wall.

2. *Restrict driving of steel piles to the June 1 to November 30 work window, or as otherwise recommended by NMFS (driving of concrete piles would not be subject to this condition).*
3. *Avoid installation of any piles during the Pacific herring spawning season of December through February. Consult with the CDFG regarding actual spawning times if pile installation occurs between October and April.*
4. *If steel piles must be driven with an impact hammer, an air curtain shall be installed to disrupt sound wave propagation, or the area around the piles being driven shall be dewatered using a cofferdam. The goal of either measure is to disrupt the sound wave as it moves from water into air.*
5. *If an air curtain is used, a qualified biologist shall monitor pile driving to ensure that the air curtain is functioning properly and Project-generated sound waves do not exceed the threshold of 180-decibels generating 1 micropascal (as established by NMFS guidelines). This shall require monitoring of in-water sound waves during pile driving.*
6. *Unless the area around the piles is dewatered during pile driving, a qualified biologist shall be present during driving of steel piles to monitor the work area for marine mammals. Driving of steel piles shall cease if a marine mammal approaches within 250 feet of the work area or until the animal leaves the work area of its own accord.*

Mitigation measure MM BI-9b would reduce the effects of pile driving-related activities by recommending the type of piles to use to minimize sound impacts, provide for an alternative method of installation to minimize sound impacts, requiring installation during an agency-approved construction window when fish are least likely to be present and thus avoid the bulk of potential impacts, and require a construction monitor to ensure all measures, including sound monitoring are complied with. This measure would not be required for the Yosemite Slough bridge if piles were driven in dry conditions behind coffer dams, as is proposed, no aquatic pressure waves would be generated. Implementation of this mitigation measure would reduce potential adverse effects to less-than-significant levels.

Impact BI-10: Mollusks

Impact of Candlestick Point

Impact BI-10a **Construction at Candlestick Point would require the removal of hard substrates (riprap) used by native oysters, but would not have a substantial adverse effect, either directly or through habitat modifications, on this species. (Less than Significant) *[Criterion N.a]***

Development at Candlestick Point would require limited in-water work. This work would be associated with the shoreline treatments; specifically, the placement of additional (rock) rip-rap, ACB mats, and/or marsh soils to improve the existing riprap shoreline edge for the purpose of reducing shoreline erosion and flooding and improving shoreline habitat. Shoreline treatments would require the removal of some substrate in areas where the Bay is eroding the existing shoreline. In these areas, hard substrates suitable for oyster settlement (rock, riprap, sheet pile, etc) would be removed, potentially directly impacting native oysters. However, in many areas, the same shoreline treatments would entail replacement of this substrate with a similar material that would also be suitable for oyster settlement. These shoreline improvements would temporarily affect substrate used by native oysters; however, habitat for substrate would be replaced with equal amounts of equivalent habitat after the treatments are complete. This would not substantially

reduce populations or available habitat. Consequently, Candlestick Point would not have a substantial adverse effect on native oysters. Impacts would be less than significant, and no mitigation is required.

In other areas, particularly along the northern edge of the Candlestick Point shoreline, the placement of ACB mats and/or marsh soils to enhance marsh development could result in the replacement of hardened substrate that may currently provide settlement habitat for oysters with softer marsh substrate that would not support oysters. No large concentrations of oysters are known to occur along the Candlestick Point shoreline, and thus marsh restoration is not expected to result in substantial declines in oyster abundance. Restoration of salt marsh along the Candlestick Point shoreline would increase the input of organic material in the area to some extent, and improvement of the shoreline would reduce erosion, which currently produces turbidity that is likely detrimental to native oysters. Thus, these shoreline improvements would confer some benefits to oysters.

Impact of Hunters Point Shipyard Phase II

Impact BI-10b **Construction at HPS Phase II would require removal of hard substrates (docks, riprap, seawalls, pilings, etc) used by native oysters, but would not have a substantial adverse effect, either directly or through habitat modifications, on this species. (Less than Significant) *[Criterion N.a]***

Native oysters are typically found on hard substrates (rock, pilings, breakwaters, etc.) in shallow intertidal and subtidal habitats along the shoreline of the Bay. Any actions that would require the modification of existing hard substrates would have the potential to impact native oysters. Implementation of the Project would also remove small sections of Piers 1, 2, and 3 to separate them from the shore and prevent public access (refer to Figure II-4 [Proposed Land Use Plan]). Those piers provide pilings that are considered a suitable substrate for oyster settlement and thus could be supporting native oysters[821]. The removal of this small section of the piers would, therefore, result in the loss of a very small amount of oyster habitat and potentially of individual oysters. In addition, the Project also includes plans to repair portions of existing seawall structures, place buttress fill (below the water surface) for structural stability of seawall structures, and modify several piers and drydocks along the shoreline of HPS Phase II. These shoreline improvements could affect native oysters and their habitat. As discussed for Candlestick Point above, the end result of shoreline improvements in some areas would be hard substrate similar to what is currently present, and thus equally suitable for oyster colonization. In other areas, the placement of ACB mats and/or marsh soils to enhance marsh development could result in the replacement of hardened substrate that may currently provide settlement habitat for oysters with softer marsh substrate that would not support oysters. These shoreline improvements would temporarily affect substrate used by native oysters, but would not substantially reduce populations or available habitat. Consequently, construction activities at HPS Phase II would not have a substantial adverse effect on native oysters.

In addition, the Project proposes to create a new marina, which would require installation of two breakwater sections (ranging between 300 and 650 feet in length)[822] that would provide suitable settlement habitat for

[821] Couch, D., and T.J. Hassler. 1989. Species profiles: life histories and environmental requirements of coastal fishes and invertebrates (Pacific Northwest)—Olympia oyster. US Fish and Wildlife Service Biol. Rep. 82(11.124). US Army Corps of Engineers, TR EL-82-4. 8 pp.
[822] Devick, Christopher, Moffat-Nichol email to Therese Brekke of Lennar Urban and Terri Vitar of PBS&J regarding length of marina breakwater, dated July 23, 2009.

native oysters. Consequently, HPS Phase II construction would result in a series of offsetting impacts; temporary impacts associated with the removal of suitable oyster habitat, followed by the replacement of these areas with new suitable habitat. The new breakwaters would be considered suitable habitat for oyster settlement equating to about 0.10 acre of new habitat. In addition, the construction of approximately 5,700 feet of a floating dock system and 80 feet of gangways that would also provide new suitable habitat for oyster settlement. Therefore, although temporary impacts to oyster habitat would occur during construction, HPS Phase II effects on native oysters would be less than significant and no mitigation is required.

Impact of Yosemite Slough Bridge

Impact BI-10c **Construction of the Yosemite Slough bridge may require removal of hard substrates (docks, riprap, seawalls, pilings, etc) used by native oysters, but would not have a substantial adverse effect, either directly or through habitat modifications, on this species. (Less than Significant)** ***[Criterion N.a]***

Construction of the Yosemite Slough bridge may result in the removal of or modifications to a small amount of riprap where the bridge abutments would be located. Riprap below the MHW elevation may be used by native oysters. However, riprap would also be placed near the abutments once they are constructed, thus replacing any oyster substrate that is temporarily impacted or removed. Furthermore, the bridge piers would provide a hard substrate that could potentially serve as substrate for oyster colonization. Thus, the construction of the Yosemite Slough bridge would not result in the permanent loss of oyster habitat, and could instead result in a net gain in potential substrate for oysters at that location. Therefore, although temporary impacts to oyster habitat would occur during construction, the Yosemite Slough bridge would not have a substantial adverse effect on native oysters. Impacts would be less than significant, and no mitigation is required.

Impact BI-11: Special-status Fish

Impact of Candlestick Point

Impact BI-11a **Construction at Candlestick Point would not have a substantial adverse effect on designated critical habitat for green sturgeon and Central California Coast steelhead, and would not result in impacts to individuals of these species as well as Chinook salmon and longfin smelt through disturbance and loss of aquatic and mudflat habitat as a result of construction of shoreline revetments. (Less than Significant with Mitigation)** ***[Criteria N.a and N.d]***

Development at Candlestick Point would require minor in-water work associated with the shoreline treatments. Work in these areas would require the repair of existing shoreline protection measures. All work would occur in relatively shallow water areas that are unlikely to support foraging special-status fish.[823] Still, the NMFS has considered the entire Bay in the site vicinity to be designated critical habitat for the green sturgeon and Central California Coast steelhead, and there is some possibility that individuals of these species, as well as other special-status fish such as Chinook salmon and longfin smelt, could be impacted by shoreline construction activities.

[823] Proposed Designation of Critical Habitat for the Southern Distinct Population Segment of North American Green Sturgeon, Draft Biological Report, National Marine Fisheries Service, September 2008.

Construction of shoreline protection measures would primarily entail the reconstruction of the existing shoreline. The new shoreline treatments would be designed to reduce erosion of the shoreline, and thus existing turbidity impacts from coastal erosion would be reduced by the Project. Some additional fill would be placed below the MHW elevation to reduce the slope of the shoreline, thus providing more beach and marsh habitat, following construction of the revetments. As a result, there would be a net decrease of approximately 0.42 acre of open waters along the shoreline of Candlestick Point. In addition, temporary impacts to aquatic habitat of these species, including designated critical habitat for the green sturgeon and Central California Coast steelhead, would occur as a result of increased turbidity and movement of materials within aquatic habitat along the shoreline during construction. Because of the regional rarity of these special-status fish, any impacts to individuals or to habitat used by these fish would be significant.

Implementation of mitigation measures MM BI-4a.1 and MM BI-4a.2 (described above) would reduce the effects of construction-related activities to aquatic habitat by mitigating for the temporary and permanent loss of jurisdictional waters from the Project as a whole by requiring compensatory mitigation (i.e., creation and/or restoration), obtaining permits from the USACE, SFRWQCB, BCDC, and other agencies as applicable that are designed to protect wetlands and jurisdictional waters, and implementing construction BMPs to reduce and/or prevent impacts to waters of the United States, including aquatic habitats.

- Implementation of mitigation measure MM BI-12a.1 and MM BI-12a.2 would reduce effects of construction activities on special-status fish by avoiding in-water construction during periods when sensitive species are most likely to be present in waters of the Project site and by educating construction personnel regarding measures to be implemented to protect fish and their habitats. Implementation of these mitigation measures would minimize any adverse effects on aquatic habitat of special-status fish, including designated critical habitat for the green sturgeon and Central California Coast steelhead, during construction and compensate for any residual impacts to these species' habitats resulting from the Project as a whole, thus reducing impacts to special-status fish to less-than-significant levels.

Impact of Hunters Point Shipyard Phase II

Impact BI-11b **Construction at HPS Phase II would not have a substantial adverse effect on designated critical habitat for green sturgeon and Central California Coast steelhead, and would not result in impacts to individuals of these species as well as Chinook salmon and longfin smelt through temporary and permanent disturbance of aquatic and mudflat habitat during construction of shoreline revetments. (Less than Significant with Mitigation)** ***[Criteria N.a and N.d]***

Construction activities at HPS Phase II include elements that would impact designated critical habitat for green sturgeon and Central California Coast steelhead within the Bay, and there is some possibility that individuals of these species, as well as other special-status fish such as Chinook salmon and longfin smelt, could be impacted by these activities as well. Construction of the proposed marina (including breakwaters) in what is now open water would result in the loss of habitat for these special-status fish species. Construction of shoreline treatments and placement of fill in other locations around the perimeter of HPS would also affect a small amount of shallow, relatively low-quality foraging habitat for green sturgeon and steelhead, as discussed for Candlestick Point in Impact BI-11a above. Consequently, these elements of the Project would impact existing critical habitat for green sturgeon and Central California Coast steelhead.

Because of the regional rarity of all these special-status fish, any impacts to individuals or to habitat used by these fish would be significant.

Some Project features would reduce the Project's impacts to these special-status fish species and designated critical habitat. Some areas of shoreline that are currently sheet-pile walls would be modified, and portions of several piers would be removed to provide new aquatic habitat that could be used by these fish. A net increase of approximately 8 acres of new aquatic habitat would result. Furthermore, the new shoreline treatments would be designed to reduce erosion of the shoreline, and, thus, existing turbidity impacts from coastal erosion would be reduced by the Project.

Compensatory mitigation for impacts to aquatic habitat, which include habitat used by green sturgeon, Central California Coast steelhead, Chinook salmon, and longfin smelt, would be provided as described by mitigation measure MM BI-4a.1, and mitigation measure MM BI-4a.2 shall be implemented to minimize impacts to wetlands, aquatic habitats, and water quality during construction. Implementation of mitigation measure MM BI-12a.1 and MM BI-12a.2 would reduce effects of construction activities on special-status fish by avoiding in-water construction during periods when sensitive species are most likely to be present in waters of the Project site and by educating construction personnel regarding measures to be implemented to protect fish and their habitats. Implementation of these measures would reduce potential adverse effects on special-status fish species to less-than-significant levels.

Impact of Yosemite Slough Bridge

Impact BI-11c **Construction of the Yosemite Slough bridge would not have a substantial adverse effect on designated critical habitat for green sturgeon and Central California Coast steelhead and would not result in impacts to individuals of these species, Chinook salmon, or longfin smelt through disturbance or loss of aquatic and mudflat habitat as a result of construction of shoreline revetments. (Less than Significant with Mitigation)** ***[Criteria N.a and N.d]***

Construction of the Yosemite Slough bridge would impact designated critical habitat for green sturgeon and Central California Coast steelhead through the construction of pilings required to support the bridge. Bridge impact areas are relatively shallow intertidal mud flats that are likely not suitable foraging habitat for either species. Those areas are likely too shallow to meet the depth or food PCEs for sturgeon and should not be considered critical habitat. Specifically, NMFS's own studies show that for juvenile green sturgeon in the Delta, relatively large numbers of juveniles were captured primarily in shallow waters from 1 to 3 meters (approximately 3.3 to 10 feet deep), indicating juveniles likely prefer depths deeper than those within the majority of the proposed bridge construction footprint for rearing and foraging.[824] Nevertheless, it is possible that green sturgeon and Central California Coast steelhead, and possibly other special-status fish such as Chinook salmon and longfin smelt, could forage in the vicinity of the proposed bridge during high tides. Therefore, construction of the bridge could impact these species due to temporarily increased turbidity and modification of mudflat habitat during construction and permanent loss of 0.11 acre of mudflat and aquatic habitat in the footprints of the bridge piers. In addition, shading from the bridge could adversely affect aquatic and mud flat habitat, and fish that use these habitats, under the bridge (refer to

[824] Proposed Designation of Critical Habitat for the Southern Distinct Population Segment of North American Green Sturgeon, Draft Biological Report, National Marine Fisheries Service, September 2008.

Impact BI-4c). Because of the regional rarity of all these special-status fish, any impacts to individuals or to habitat used by these fish would be significant.

As described under Impact BI-11b above, some Project components would benefit these fish by increasing the extent of open water in the Project area through removal of existing structures and by reducing coastal erosion. In addition, compensatory mitigation for impacts of the bridge to aquatic habitat would be provided as described by mitigation measure MM BI-4a.1 and MM BI-4c, and mitigation measure MM BI-4a.2 shall be implemented to minimize impacts to wetlands, aquatic habitats, and water quality during construction. Implementation of mitigation measure MM BI-12a.1 and MM BI-12a.2 would reduce effects of construction activities on special-status fish by avoiding in-water construction during periods when sensitive species are most likely to be present in waters of the Project site and by educating construction personnel regarding measures to be implemented to protect fish and their habitats. Implementation of these measures would reduce potential adverse effects on special-status fish species to less-than-significant levels.

Impact BI-12: Essential Fish Habitat

Impact of Candlestick Point

Impact BI-12a **Construction at Candlestick Point would not have a substantial adverse effect on designated essential fish habitat through (EFH) or result in a substantial change in total available essential fish habitat through placement of riprap and other fill or through temporary water-quality impacts during construction. EFH is a sensitive natural community identified in local or regional plans, policies, and regulations or by the CDFG or USFWS. (Less than Significant with Mitigation)** ***[Criterion N.b]***

The Bay adjacent to the Project site has been designated EFH in the Pacific Coast Salmon Plan,[825] Coast Pelagics Fishery Management Plan,[826] and Pacific Groundfish Fishery Management Plan.[827] These management plans include species such as northern anchovy (*Engraulis moradax*), Pacific herring, Pacific sardine, Chinook salmon, and a dozen species of groundfish [i.e., starry flounder (*Platichthys stellatus*), English and sand sole (*Parophrys vetulus* and *Psettichthys melanostictus* respectively), leopard shark (*Triakis semifasciata*), lingcod (*Ophidon elongates*), cabezone (*Scorpaenichthys marmoratus*), and various rockfish]. The only in-water portions of Candlestick Point are associated with shoreline treatments. Installation of shoreline treatments that require modification of the substrate within the Bay would be considered to result in changes to designated EFH. Installation of shoreline treatments would modify EFH due to modification of mudflat habitat and increased turbidity during construction. As shown in Table III.N-4, approximately 4.98 acres of aquatic habitat that would be considered EFH will be impacted by the project. The majority of these impacts would be temporary, as they would occur during replacement of the existing revetment

825 PFMC (Pacific Fisheries Management Council) 2003. Pacific Coast Salmon plan: Fishery management plan for commercial and recreational fisheries off the coasts of Washington, Oregon, and California as revised through amendment 14.
826 PFMC (Pacific Fisheries Management Council) 1998. The coastal pelagic species fishery management plan. As amended through 2006.
827 PFMC (Pacific Fisheries Management Council) 2008. Pacific coast groundfish fishery management plan for the California, Oregon, and Washington groundfish fishery as amended through amendment 19.

with similar structures. However, as described in Impact BI-11a above, these activities would result in a net decrease of approximately 0.42 acre of open waters along the shoreline of Candlestick Point. Although the EFH that would be temporarily impacted by construction at Candlestick Point represents a minute fraction of available EFH in the Bay, this impact would be substantial, in the absence of mitigation, due to the importance of EFH to the ecology of the Bay.

Impact BI-2 above described the less-than-significant impact of the Project to common fish, shellfish, and mollusks. Although impacts to the populations of common aquatic species would be less than significant, as described in Impact BI-2, construction at Candlestick Point would be considered to have a substantial adverse effect on EFH overall because the function of that habitat would be altered by the Project, potentially having longer-term consequences on aquatic habitat for both common and special-status aquatic species. Any loss of EFH that would result from construction activities at Candlestick Point would be mitigated via the compensatory mitigation for impacts to jurisdictional waters (mitigation measure MM BI-4a.1), and measures to avoid and minimize adverse effects to aquatic habitats, described in mitigation measure MM BI-4a.2, would further reduce potential adverse effects to EFH. To reduce this potential impact to less-than-significant levels, the following mitigation measures would also be implemented.

MM BI-12a.1 *Seasonal Restrictions on In-Water Work. In-water work when juvenile salmonids are moving through the estuary on the way to the ocean or when groundfish and prey species could be directly impacted shall be avoided. Because steelhead are potentially present, the allowed dredge window for this area of the San Francisco Bay is June 1 through November 30.*[828] *All in-water construction shall occur during this window. If completion of in-water work within this period is not feasible due to scheduling issues, new timing guidelines that shall be established and submitted to NMFS and CDFG for review and approval.*

MM BI-12a.2 *Worker Training. Personnel involved in in-water construction and deconstruction activities shall be trained by a qualified biologist (experienced in construction monitoring, as approved by the City/Agency) in the importance of the marine environment to special-status fish, birds, and marine mammals and the environmental protection measures put in place to prevent impacts to these species, their habitats, and Essential Fish Habitat. The training shall include, at a minimum, the following:*

- *A review of the special-status fish, birds, and marine mammals and sensitive habitats that could be found in work areas*
- *Measures to avoid and minimize adverse effects to special-status fish, birds, marine mammals, their habitats, and Essential Fish Habitat*
- *A review of all conditions and requirements of environmental permits, reports, and plans (i.e., USACE permits)*

Mitigation measure MM BI-12a.1 would reduce the effects of construction-related activities to EFH by establishing a construction window that would minimize impacts to fish by avoiding migration and breeding periods, and mitigation measure MM BI-12a.2 would ensure that personnel involved in construction and deconstruction activities are trained on measures to avoid and minimize adverse effects to special-status aquatic species and their habitats. Implementation of these mitigation measures, along with mitigation measures MM BI-4a.1 and MM BI-4a.2, would reduce potential adverse effects on EFH at Candlestick Point to less-than-significant levels.

[828] LTMS Environmental Work Windows Work Group. LTMS Informal work windows, Informal consultation preparation packet. Draft version 1.4. February 2004. Website: http://www.spn.usace.army.mil/conops/informal.pdf.

Impact of Hunters Point Shipyard Phase II

Impact BI-12b **Construction at HPS Phase II would not have a substantial adverse effect on designated essential fish habitat through (EFH) through placement of riprap and other fill, or through temporary water-quality impacts during construction. EFH is a sensitive natural community identified in local or regional plans, policies, and regulations or by the CDFG or USFWS. (Less than Significant with Mitigation) *[Criterion N.b]***

The same three fishery management plans and the species covered in those plans discussed in the previous impact statement apply to HPS Phase II. The modifications to EFH that could arise from HPS Phase II are associated with the proposed marina, placement of rock fill to buttress existing bulkheads, and the shoreline treatments. Marina operations could affect EFH through potential impacts to water quality and fish habitat resulting primarily from spills or intentional discharges of fuel or other harmful substances from boats using, or fueling facilities associated with, the marina. The most substantial loss of EFH would result from the placement of rock buttress fill necessary to protect the integrity of existing bulkheads. Although aquatic habitat would remain above the buttresses, this rock would occupy existing fish habitat, and the Project would thus substantially modify EFH within the waters adjacent to the HPS Phase II site.

Overall, activities at HPS Phase II will affect 21.11 acres of aquatic habitat that would be considered EFH. However, in addition to activities resulting in fill of EFH, the Project also includes the removal of some shoreline structures (i.e., piers and/or bulkheads) and fill material that are currently present in jurisdictional areas. For example, portions of the Re-gunning pier and edges of bulkheads along much of the eastern part of HPS Phase II would be removed to create new open-water habitat. Although these areas are considered permanently impacted for the purposes of this impact assessment, since some fill would be placed along the new shoreline of these bulkheads for stabilization and restoration purposes, removal of structures and fill would restore approximately 8 acres of new aquatic habitat, more than offsetting the loss of EFH resulting from placement of fill for buttresses.

Other elements of HPS Phase II construction that could affect EFH are the shoreline treatments. Repairs to the seawall and other shoreline treatments proposed for HPS Phase II would result in modifications to EFH, both due to modification of substrate and mobilization of sediments during construction, but because these impacts are primarily temporary, are localized and often replace an existing failing structure with a similar structure, these repairs would not result in a substantial modification of the function of existing EFH. Also, shoreline improvements along the southern edges of HPS would reduce coastal erosion and associated turbidity, resulting in a long-term benefit to water quality and EFH. Collectively, these repairs and improvements of the Project are not considered to result in a substantial reduction in designated EFH.

Impact BI-2 above described the less-than-significant impact of the Project to common fish, shellfish, and mollusks. Although impacts to the populations of common aquatic species would be less than significant, as described in Impact BI-2, the HPS Phase II development would be considered to have a substantial adverse effect on EFH overall because the function of that habitat would be altered by the Project, potentially having longer-term consequences on aquatic habitat for both common and special-status aquatic species. Any loss of EFH that would result from construction activities at HPS Phase II would be mitigated via the compensatory mitigation for impacts to jurisdictional waters (mitigation measure

MM BI-4a.1) and, if necessary, mitigation for impacts to eelgrass (mitigation measure MM BI-5b.3). Measures to avoid and minimize adverse effects to aquatic habitats and eelgrass beds, described in mitigation measures MM BI-4a.2 and MM BI-5b.1 through MM BI-5b.4, would further reduce potential adverse effects to EFH. The measures described above to mitigate impacts to EFH at Candlestick Point (MM BI-12a.1 and MM BI-12a.2) will be implemented at HPS Phase II as well. Because activities at HPS Phase II involve more in-water work than at Candlestick Point, and involve the demolition of existing structures in and immediately adjacent to EFH, the following additional mitigation measures will also be implemented at HPS Phase II to reduce potential impacts to less-than-significant levels.

MM BI-12b.1 *Essential Fish Habitat Avoidance and Minimization Measures. The following mitigation measures have been adapted from Amendment 11 of the West Coast Groundfish Plan[829] and Appendix A of the Pacific Coast Salmon Plan.[830] Incorporation of the following, or equivalent mitigation as otherwise required by the USACE or NMFS, would reduce the impacts to Essential Fish Habitat (EFH) to a level considered less than significant. Unless modified by the federal permitting agencies (NMFS or USACE), these measures shall be implemented during construction by the Project Applicant. Any reporting required shall be specified in the USACE permits and reports shall be submitted to the USACE and NMFS.*

- *If dredging is required, permits will be obtained through the Dredged Material Management Office (DMMO) process, and the following mitigation from the Long-Term Management Strategy (LTMS) shall be implemented:*
  - *Dredging shall avoid areas with submerged aquatic vegetation (eelgrass beds or other EFH areas of particular concern) especially where the action could affect groundfish, prey of outmigrating juvenile salmon or groundfish, larval marine species, or habitat for native oysters*
  - *Sediments shall be tested for contaminants as per EPA and USACE requirements. Contaminated sediments shall be disposed of in accordance with EPA and USACE guidelines*
  - *Slopes of the dredged area shall be gradual enough so that sloughing is unlikely to occur. Verification of these conditions shall be achieved through follow-up bathymetric surveys*
  - *To minimize turbidity and potential resuspension of contaminated sediments, dredging shall use suction equipment, or similar equipment, when feasible. Where an equipment type may generate significant turbidity (i.e., clamshell), dredging shall be conducted using adequate engineering and best management practices to control turbidity. These include, but are not limited to, sediment curtains and tidal work windows.*
- *All construction equipment used in conjunction with in-water work (pipelines, barges, cranes, etc.) shall avoid wetlands, marshes, and areas of subaquatic vegetation (including eelgrass beds)*
- *Upland disposal options shall be considered for all spoils generated by on-site construction, especially if high levels of contaminants are present*
- *Maximize the use of clean dredged material for beneficial use opportunities, such as salt marsh restoration*
- *Use Best Management Practices (BMPs) for controlling pollution from marina operations, boatyards, and fueling facilities that meet, as applicable, the BMPs listed in the National*

[829] PFMC 1998. Essential Fish Habitat – West Coast Groundfish, Amendment 11.
[830] PFMC 1999. Appendix A: Identification and description of Essential Fish Habitat, Adverse Impacts, and Recommended Conservation Measures for Salmon. *In* Pacific Coast Salmon Plan (1997) as amended through Amendment 14. Website: http://www.pcouncil.org/salmon/salfmp/a14.html.

Management Measures to Control Nonpoint Source Pollution from Marinas and Recreational Boating[831]

MM BI-12b.2 *Deconstruction/Construction Debris Recovery. A Seafloor Debris Minimization and Removal Plan shall be prepared by the Project Applicant and approved by the City/Agency, prior to initiation of in-water deconstruction (dismantling) or construction activities. The Plan shall be implemented during in-water deconstruction or construction activities, and such activities shall be monitored by a qualified biologist who is experienced in construction monitoring (as approved by the City/Agency). The Seafloor Debris Minimization and Removal Plan shall include, at a minimum:*

- *Debris field boundaries associated with deconstruction activities*
- *Identification of measures taken to minimize the potential for debris to fall into aquatic habitats (i.e., the use of netting below in-water construction or deconstruction areas)*
- *Deconstruction equipment, tools, pipes, pilings, and other materials or debris that are inadvertently dropped into the Bay, along with their descriptions and locations*
- *Circumstances requiring immediate cessation of deconstruction activities and immediate initiation of search and recovery efforts, including procedures for implementing those recovery efforts*
- *How lost debris that is to be removed post-deconstruction is to be identified, who will be conducting search and recovery operations, and the survey methods to be employed to locate lost equipment and materials*
- *Criteria that will be used to:*
  - *Determine whether recovery efforts are appropriate for the object being recovered and do not result in potential environmental impairment greater than if the debris was allowed to remain in place*
  - *When sufficient effort has been expended to recover a lost object(s) with no success and continued efforts to recover the seafloor debris have diminishing potential for success and/or result in environmental impairment greater than leaving the debris in place*
- *Person(s) responsible for implementing the Plan and making the determination on the type of recovery required*
- *How debris is to be disposed of or recycled*
- *Metrics for determining when recovery efforts will be considered complete*

Following completion of all post deconstruction recovery efforts for seafloor debris, a report shall be prepared by the Project Applicant and submitted to the City/Agency detailing, at a minimum, (1) recovery activities during deconstruction and post-deconstruction, (2) listings of all lost and recovered debris, (3) final disposition of recovered debris, and (4) discussion of what debris could not be recovered and why.

Mitigation measure MM BI-12b.1 would reduce the effects of construction-related activities to EFH by avoiding areas with submerged vegetation thereby protecting habitat, and managing construction equipment with Best Management Practices to prevent contamination. Mitigation measure MM BI-12b.2 would mandate the creation and implementation of a Seafloor Debris Removal Plan. This Plan shall include sufficient environmental protection measures to ensure effective recovery of lost Project debris and minimize potential environmental impacts posed by the debris, or debris recovery to designated EFH or other sensitive Bay habitats and biota (i.e., critical habitat and herring spawning habitats). Implementation of these mitigation measures would reduce potential adverse effects on EFH at HPS Phase II to less-than-significant levels.

[831] National Management Measures to Control Nonpoint Source Pollution from Marinas and Recreational Boating. EPA 841-B-01-005, November 2001.

Impact of Yosemite Slough Bridge

Impact BI-12c **Construction of the Yosemite Slough bridge would not have a substantial adverse effect on designated essential fish habitat through (EFH) through placement of riprap and other fill, or through temporary water-quality impacts during construction. EFH is a sensitive natural community identified in local or regional plans, policies, and regulations or by the CDFG or USFWS. (Less than Significant with Mitigation)** ***[Criterion N.b]***

Construction of the Yosemite Slough bridge would impact EFH through the construction of pilings required to support the bridge. As detailed in Table III.N-4, the amount of area impacted is approximately 1.28 acres of temporary impacts and 0.40 acre of permanent impacts, which includes both on site and off site areas. These impacts would have a substantial adverse effect on EFH because the function of portions

- of the impacted habitat would be permanently altered by the Project, a significant impact. In addition, shading from the bridge could adversely affect aquatic and mud flat habitat, and fish that use these habitats, under the bridge (refer to Impact BI-4c).

- Any loss or modification of EFH that would result from the Yosemite Slough bridge would be mitigated via the compensatory mitigation for impacts to jurisdictional waters (mitigation measure MM BI-4a.1 and MM BI-4c). Measures to avoid and minimize impacts to aquatic habitats, described in mitigation measure MM BI-4a.2, would further reduce impacts to EFH. To reduce these potential impacts to less-than-significant levels, mitigation measures MM BI-12a.1, MM BI-12a.2, MM BI-12b.1, and MM BI-12b.2 would be implemented. Mitigation measure MM BI-12a.1 would reduce the effects of construction-related activities to EFH by establishing a construction window that would minimize impacts to fish by avoiding migration and breeding periods. Mitigation measure MM BI-12a.2 would ensure that personnel involved in deconstruction activities are trained on measures to avoid and minimize adverse effects to special-status aquatic species and their habitats. Mitigation measure MM BI-12b.1 would avoid areas with submerged vegetation thereby protecting habitat and manage construction equipment with Best Management Practices to prevent contamination. Mitigation measure MM BI-12b.2 would mandate the creation and implementation of a Seafloor Debris Removal Plan. This Plan shall include sufficient environmental protection measures to ensure effective recovery of lost Project debris and minimize potential environmental impacts posed by the debris, or debris recovery to designated EFH or other sensitive Bay habitats and biota (i.e., critical habitat and herring spawning habitats). Implementation of these mitigation measures would reduce potential adverse effects on EFH in Yosemite Slough to less-than-significant levels.

Impact BI-13: Wildlife Movement

Impact of Candlestick Point

Impact BI-13a **Construction at Candlestick Point would not interfere substantially with the movement of native resident or migratory wildlife species or with established native resident or migratory wildlife corridor, or impede the use of native wildlife nursery sites. (Less than Significant)** ***[Criterion N.d]***

As discussed in the Setting section, surveys of Candlestick Point and review of background studies did not identify any regional wildlife corridor or migratory pathways. The site is surrounded by open water and urban development and no major drainages, canyon bottoms, ridgetops, rivers, creeks or areas that provide

substantial movement corridors or migratory pathways occur within Candlestick Point. No areas that would be considered nursery sites, which generally include some types of wetlands and avian rookeries, are found within Candlestick Point. The area surrounding Candlestick Point is part of the San Francisco Bay estuary, and the areas of the estuary affected by the Candlestick Point portion of the Project would be the existing shoreline structures. These structures would be replaced with new similar structures that would be designed to provide even higher-quality habitat for wildlife, including estuarine species, than the existing shoreline. In addition, although migratory fish could move though the open water and tidal portion of the site, Candlestick Point does not contain any migratory fish pathways such as anadromous fish streams or rivers (fish that breed in freshwater and spend adult lives in the ocean) and Project construction would not fragment habitat or create substantial barriers to movement though the adjacent waters. Consequently, construction at Candlestick Point would affect primarily terrestrial species well adapted to human disturbance that move locally within the Project site and the adjacent habitat patches. These common ground-dwelling vertebrates forage for food, mate, and move between habitat patches within the site and typically have small ranges that would limit their movement to localized use. Construction at Candlestick Point would not substantially interfere with this local movement as the wildlife would be able to continue their pre-Project activities in the areas not under construction, and construction would not permanently bar their movement through those portions of the site. Consequently, as the Project would not interfere substantially with the movement of native resident or migratory wildlife species, established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites, impacts would be less than significant. No mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact BI-13b **Construction at HPS Phase II and construction of the Yosemite Slough bridge would not interfere substantially with the movement of native resident or migratory wildlife species or with established native resident or migratory wildlife corridors, but it could impede the use of native wildlife nursery sites. (Less than Significant with Mitigation) *[Criterion N.d]***

As discussed in the Setting section, surveys of HPS Phase II did not identify any regional wildlife corridor or migratory pathways. The site is surrounded by open water and urban development and no major drainages, canyon bottoms, ridgetops, rivers, creeks or areas that provide substantial movement corridors or migratory pathways occur within HPS Phase II. Consequently, construction at HPS Phase II would affect primarily terrestrial species that are well adapted to human disturbance in the area and move locally within the Project site and between the adjacent habitat patches. These common ground-dwelling vertebrates forage for food, mate, and move between habitat patches within the site and typically have small ranges that would limit their movement to localized use. Construction of HPS Phase II would not substantially interfere with this local movement as the terrestrial wildlife would be able to continue their pre-Project activities in the areas not under construction, and construction would not permanently bar their movement through those portions of the site as the construction activities would be temporary.

The Yosemite Slough bridge would separate the upper part of Yosemite Slough, including the proposed restoration site, from South Basin and San Francisco Bay. This structure would not, however, substantially reduce the ability of fish or wildlife that currently move in and out of Yosemite Slough to continue doing so. The bridge's low, flat profile would allow birds to easily fly over the bridge between the upper part of

the slough and South Basin, but the bottom of the bridge deck is high enough to allow swimming birds such as ducks to swim under the bridge when tidal conditions would currently permit such movements. The bridge's piers would occupy only a very small fraction of the aquatic habitat within the bridge footprint, and thus fish and other aquatic species would be able to easily move in and out of the slough even after the bridge is constructed. Although the bridge and the road crossing it would impede movement of terrestrial species from one side of the bridge to the other, sufficient terrestrial space would be present above the high tide line at the abutments to allow terrestrial wildlife to pass under the bridge. Consequently, Project activities within HPS Phase II and Yosemite Slough would not substantially interfere with the movement of any native resident or migratory terrestrial species.

With respect to aquatic species, although migratory fish could move through the open water and the Yosemite Slough, HPS Phase II does not contain any substantial migratory fish pathways such as anadromous fish (fish that breed in freshwater and spend adult lives in the ocean) streams or rivers and Project construction, including the Yosemite Slough bridge, would not further fragment habitat or create substantial barriers to movement though the adjacent waters such to prevent aquatic species from moving freely along the coastline. However, as discussed in Impact BI-5b, construction of HPS Phase II components such as breakwaters and other shoreline treatments would occur near eelgrass beds, which could remove them or indirectly impact them such that productivity and survival of these habitats would be reduced. Eelgrass communities are considered important aquatic nursery sites as they serve as a haven for numerous aquatic species. Elimination of these important nursery areas would be a significant impact, as it would substantially impede the use of the only two patches of eelgrass habitat (wildlife nursery sites) in the HPS Phase II site. To reduce these impacts, mitigation measures MM BI-5b.1 through MM BI-5b.4 would be implemented.

Implementation of mitigation measures MM BI-5b.1 through MM BI-5b.4 would reduce the effects of HPS Phase II construction on eelgrass by avoiding impacts through initial design if feasible; determining the locations of eelgrass beds through surveys; using survey data to refine shoreline treatments to further avoid or minimize impacts to eelgrass; and compensating for unavoidable impacts through the creation or restoration of eelgrass beds at a 3:1 ratio. Consequently, implementation of these measures would reduce impacts to eelgrass beds, and thus to nursery sites, to less-than-significant levels. This would ensure that construction of HPS Phase II would not interfere substantially with the use of native wildlife nursery sites. Implementation of these mitigation measures would reduce this impact to a less-than-significant level.

Impact BI-14: Local Plans and Policies

Impact of Candlestick Point

Impact BI-14a **Construction at Candlestick Point would not conflict with local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance. (Less than Significant with Mitigation) *[Criterion N.e]***

The *City of San Francisco General Plan* articulates broad policies to protect natural resources and federally and state listed species, and work with federal and state agencies. The General Plan does not identify any additional, specific resources for protection beyond those identified by federal and state agencies. This document analyzes the impacts of the project on natural resources identified for protection by such federal and state policies, and identifies mitigation measures to reduce or avoid significant impacts. The Project would not, therefore, conflict with the natural resource protection policies of the General Plan.

In addition, the City has adopted an Urban Forestry Ordinance to protect street trees within the jurisdiction of the DPW, and significant and landmark trees within the jurisdiction of the DPW or on private property. Section 143 of the City's Planning Code requires the planting of street trees when constructing new buildings within specified land use districts. According to the City's registry of "landmark trees", no such trees are present on Candlestick Point or elsewhere in the Project area.[832] A tree survey[833] was conducted within all of the Project site except the portion of CPSRA that is not subject to the land transfer and is thus not subject to direct impacts from this Project. This survey identified approximately 1,976 "tree"[834] stems emanating from 1,068 individual plants on Candlestick Point. Of these, approximately 1,079 stems meet the size criteria for "significant trees", as defined by the Urban Forestry Ordinance, and any of these trees that is (1) on property under the jurisdiction of the Department of Public Works or (2) on privately owned-property with any portion of its trunk within 10 feet of the public right-of-way would be considered a significant tree. Likewise, any of the 1,976 trees on Candlestick Point growing within the public right-of-way or on land under the jurisdiction of the Department of Public Works would be considered a "street tree"; some trees meet the criteria of both significant trees and street trees. The vast majority of these trees consisted of multiple-stemmed myoporum; eucalyptus, pines, and olives were also well represented. All four of these species are non-natives.

Construction activities associated with Candlestick Point could result in disturbance or loss of trees within DPW jurisdiction. These trees would be subject to the requirements of the *Public Works Code*, which specifies a process for gaining approval to remove trees, and requires the protection of trees during construction activities. Trees approved for removal must be replaced in accordance with DPW requirements. Compliance with the City's Street Tree Ordinance will reduce impacts to trees within DPW jurisdiction to a less-than-significant level.

The removal of trees located outside of DPW jurisdiction is not subject to regulation by the *Public Works Code*. However, the removal of large numbers of trees, particularly trees that meet the size definition of significant trees, without replacement of trees, could result in conflicts with policies articulated in the City's Urban Forestry Ordinance. The ordinance identifies trees as important to the urban environment because they improve air quality and wildlife habitat, contribute to psychological well-being and the aesthetic environment, and decrease noise. The City's *Planning Code* Section 143 embodies similar policies by requiring the planting of certain quantities of street trees when constructing new development in certain areas of the City. The *Planning Code* does not automatically apply in redevelopment areas, so the development that does not include planting of street trees would conflict with the policy goals of Section 143. Mitigation measure MM BI-14a would ensure that development in Candlestick Point does not result in conflicts with these policies by requiring preservation of street trees, trees that meet the size specification of significant trees, replacement of large trees that are removed, and the planting of street trees, consistent with *Planning Code* Section 143.

---

832 http://www.sfenvironment.org/our_programs/interests.html?ssi=4&ti=8&ii=131.
833 H.T. Harvey & Associates, *Candlestick Point/Hunters Point Shipyard Tree Survey*. October 16, 2009.
834 For the purpose of this survey, any stem of a woody plant with a tree-like (as opposed to shrubby) growth habit measuring at least 2 inches in diameter at a height of 4.5 feet above the ground was considered a "tree."

MM BI-14a *Preservation and Replacement of Significant Trees, and Preservation and Planting of Street Trees. Construction activities outside of the Department of Public Works (DPW) jurisdiction could result in the disturbance or removal of a large number of trees. To minimize this impact, the following measures shall be implemented by the Project Applicant in these areas:*

1. *Avoidance of the removal of trees that meet the size specifications of significant trees in the Public Works Code Article 16 shall occur to the maximum extent feasible, and any such trees that are removed shall be replaced at a minimum of 1:1 (1 impacted:1 replaced). The species used for replacement shall be consistent with DPW recommendations.*
2. *Street trees shall be planted in all new development areas. The species, size, and locations shall be consistent with the requirements specified in Planning Code Section 143, including, but not limited to, the following:*
    a) *The street trees installed shall be a minimum of one 24-inch box tree for each 20 feet of frontage of the property along each street or alley, with any remaining fraction of 10 feet or more of frontage requiring an additional tree. Such trees shall be located either within a setback area on the lot or within the public right-of-way along such lot.*
    b) *The species of trees selected shall be suitable for the site, and, in the case of trees installed in the public right-of-way, the species and locations shall be subject to the approval by the DPW. Procedures and other requirements for the installation, maintenance, and protection of trees in the public right-of-way shall be as set forth in* Public Works Code *Article 16.*
3. *If a significant tree or street tree will not be removed, but construction activities will occur within the dripline of such trees, a Tree Protection Plan shall be prepared by an International Society of Arboriculture (ISA) certified arborist, in accordance with the Urban Forestry Ordinance. This plan shall be submitted to the Planning Department for review and approval prior to issuance of a demolition or building permit. The Tree Protection Plan shall include measures to protect all parts of a tree from disturbance during construction, and may include the following:*
    a) *A site plan with tree species, trunk location, trunk diameter at breast height, and the canopy dripline area within development*
    b) *The use of protective fencing to establish an area to be left undisturbed during construction*
    c) *Protection specifications, including construction specifications such as boring instead of trenching for utility lines, or tree specifications such as drainage, fertilization, or irrigation measures*
    d) *Pruning specifications, if needed, to preserve the health of the tree and allow construction to proceed*

Mitigation measure MM BI-14a would encourage the preservation of street trees and trees that are large enough to meet the size specification of significant trees in the *Public Works Code*, and would require the replacement of large trees that are removed. Further, it would require the planting of street trees consistent with the intent of the *Planning Code* Section 143. In addition, mitigation measure MM BI-7b includes the planting of approximately 10,000 net new trees. The planting of an estimated 10,000 net new trees would increase the number of trees in the Study Area considerably, increase canopy cover, and promote a healthy and sustainable urban forest. With implementation of mitigation measures MM BI-14a and MM BI-7b, the Project would not result in a conflict with City policies designed to protect urban streetscape through the planting of street trees. Impacts would be less than significant.

Further, the Draft Parks, Open Space, and Habitat Concept Plan (as required by mitigation measure MM BI-7b) includes the planting of approximately 10,000 net new trees, avoids removal of native trees

where feasible, and establishes new parkland and open space that would include a predominance of native species (see Impact BI-2 and Impact BI-7b). The planting of an estimated 10,000 net new trees at the Project site and in the community would increase the number of trees in the Study Area considerably, increase canopy cover, and promote a healthy and sustainable urban forest. Consequently, development of Candlestick Point would not conflict with any local policies or ordinances protecting biological resources, and overall impacts would be beneficial.

Impact of Hunters Point Shipyard Phase II

Impact BI-14b **Construction at HPS Phase II and Yosemite Slough bridge would not conflict with local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance. (Less than Significant with Mitigation) *[Criterion N.e]***

Similar to development at Candlestick Point, construction activities associated with HPS Phase II would be consistent with the policies of the *City of San Francisco General Plan* relating to biological resources. In addition, the City has adopted an Urban Forestry Ordinance to protect street trees within the jurisdiction of the DPW, and significant and landmark trees within the jurisdiction of the DPW or on private property. Section 143 of the City's Planning Code also regulates the planting of street trees associated with construction of buildings within specified land use districts. According to the City's registry of "landmark trees", no such trees are present on HPS Phase II or elsewhere in the Project area.[835] A tree survey[836] conducted for the Project identified approximately 854 "tree" stems emanating from 328 individual plants on HPS Phase II. Of these, approximately 400 stems meet the size criteria for "significant trees", as defined by the Urban Forestry Ordinance. Although most of HPS Phase II is within the jurisdiction of the Navy, if and any of these trees are (1) on property under the jurisdiction of the Department of Public Works or (2) on privately owned-property with any portion of its trunk within 10 feet of the public right-of-way, it would be considered a significant tree under the Urban Forestry Ordinance. Likewise, any of the 854 trees on HPS Phase II growing within the public right-of-way or on land under the jurisdiction of the Department of Public Works would be considered a "street tree"; some trees meet the criteria of both significant trees and street trees. Trees recorded on HPS Phase II during the tree survey were dominated by small, multi-stemmed toyon (*Heteromeles arbutifolia*; a native species, though the trees on HPS appear to be of an ornamental variety) and several non-natives, including London planetree (*Platanus* x *acerifolia*) and acacia (*Acacia* spp.).

Construction activities associated with HPS Phase II could result in disturbance or loss of trees within DPW jurisdiction, including areas outside of the Navy's property (i.e., City streets adjoining the HPS Phase II areas) or within on-site and off-site areas of Yosemite Slough (i.e., where construction of infrastructure may occur). These trees would be subject to the requirements of the *Public Works Code*, which specifies a process for gaining approval to remove trees, and requires the protection of trees during construction activities. Trees approved for removal must be replaced in accordance with DPW requirements. Compliance with the City's Street Tree Ordinance will reduce impacts to trees within DPW jurisdiction to a less-than-significant level.

[835] http://www.sfenvironment.org/our_programs/interests.html?ssi=4&ti=8&ii=131.
[836] H.T. Harvey & Associates, *Candlestick Point/Hunters Point Shipyard Tree Survey*. October 16, 2009.

The removal of trees located outside of DPW jurisdiction is not subject to regulation by the *Public Works Code*. However, the removal of large numbers of trees, particularly trees that meet the size definition of significant trees, without replacement of trees, could result in conflicts with policies articulated in the City's Urban Forestry Ordinance. The ordinance identifies trees as important to the urban environment because they improve air quality and wildlife habitat, contribute to psychological well-being and the aesthetic environment, and decrease noise. The City's *Planning Code* Section 143 embodies similar policies by requiring the planting of certain quantities of street trees when constructing new development in certain areas of the City. The *Planning Code* does not automatically apply in redevelopment areas, so the development that does not include planting of street trees would conflict with the policy goals of Section 143. Mitigation measure MM BI-14a would ensure that development in HPS Phase II does not result in conflicts with these policies by requiring preservation of street trees and trees that meet the size specification of significant trees, replacement of large trees that are removed, and the planting of street trees, consistent with *Planning Code* Section 143. Therefore, with implementation of mitigation measure MM BI-14a, impacts would be less than significant.

Further, the Draft Parks, Open Space, and Habitat Concept Plan (required by mitigation measure MM BI-7b) includes the planting of approximately 10,000 net new trees at the Project site and in the community, avoids removal of native trees where feasible, and establishes new parkland and open space that would include a predominance of native species (refer to Impact BI-2 and Impact BI-7b). The planting of an estimated 10,000 net new trees would increase the number of trees in the Study Area, increase canopy cover, and promote a healthy and sustainable urban forest. Consequently, development of HPS Phase II and construction of the Yosemite Slough bridge would not conflict with any local policies or ordinances protecting biological resources, and overall impacts would be beneficial.

Impact BI-15: Contaminated Soils or Sediments during Construction

Impact of Candlestick Point

Impact BI-15a **Construction within the shoreline or Bay at Candlestick Point would not result in the disturbance of contaminated soil or the re-suspension of contaminated sediments. (No Impact) *[Criteria N.a and N.b]***

There are no sites with known contamination requiring remediation at Candlestick Point. Therefore, fish or wildlife species, and aquatic communities would not be exposed to contaminated fill or Bay/shoreline sediments during construction activities, and there would be no impact. No mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact BI-15b **Construction within the shoreline or Bay at HPS Phase II would not result in the disturbance of contaminated soil or the re-suspension of contaminated sediments. (Less than Significant with Mitigation) *[Criteria N.a and N.b]***

As discussed in Section III.K (Hazards and Hazardous Materials) of this EIR, chemicals and radioactive materials are present in soil and groundwater in various locations throughout the HPS Phase II site at levels that require remediation. Disturbance of fill or shoreline sediments, and associated stockpiling and on-site soil movement, during construction could provide potential pathways through which fish and wildlife

species could be exposed to contaminants in fill material or Bay/shoreline sediments. Exposure of fish and wildlife to such contaminants could potentially impair the health or productivity of exposed individuals, or could have food-chain effects on species that prey upon exposed individuals through bioconcentration of contaminants. Contaminant exposure that adversely affects the health or productivity of special-status fish or wildlife species, or that adversely affects large numbers of individuals of common fish and wildlife species, would be considered a substantial adverse effect.

As discussed in Section III.K, the Navy is responsible for some remediation activities (i.e., radiological contamination) on HPS Phase II. Because contaminants have been identified in those parcels for which remedial actions have been selected but not yet implemented by the Navy, construction of shoreline improvements has the potential to disturb sediment or soil that may contain chemical contaminants. However, if the Navy does not complete its remediation activities in advance of Project activities, the San Francisco Redevelopment Agency (Agency) or the Project Applicant would implement the remaining remediation activities in conjunction with shoreline improvement activities, with appropriate regulatory oversight, as required by mitigation measure MM HZ-10b. Impact HZ-10b discusses the process that would be followed by Agency or the Project Applicant in conjunction with development activities with appropriate regulatory oversight to manage potentially contaminated sediments that could be affected by Project shoreline improvements.

In addition, as discussed in Section III.M (Hydrology and Water Quality) of this EIR, implementation of measures to control stormwater runoff during construction would control discharge of potential chemicals adhered to soil in the runoff. Mitigation measures MM HY-1a.1 and MM HY-1a.2 would require preparation of a SWPPP to identify the specific measures and BMPs that are applicable to HPS Phase II construction activities in the event of a spill of construction materials or exposure of hazardous materials. This would reduce the likelihood of contaminants being conveyed to near-shore and offshore environments, which would reduce the risk to the aquatic environment and species that rely on that habitat (e.g., birds and mammals).

Implementation of mitigation measures MM HZ-10b, MM HY-1a.1, and MM HY-1a.2 would reduce the exposure of fish or wildlife to contaminated fill or Bay/shoreline sediments during construction activities, and adverse effects would be less than significant.

Operational Impacts

Impact BI-16: Sensitive Birds and Marine Mammals

Impact of Candlestick Point

Impact BI-16a **Implementation of the Project at Candlestick Point would not have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS or interfere substantially with the movement of any native resident or migratory fish, or impede the use of native wildlife nursery sites. (Less than Significant)** ***[Criteria N.a and N.d.]***

Operation of the development at Candlestick Point does not contain an in-water operational component and would not impact birds or marine mammals within the waters of the Bay. There are no known marine mammal pupping sites or major haulout locations within Candlestick Point where animals would be subject to increased disturbance during operation. Consequently, operation of Project components at Candlestick Point would not have a substantial adverse effect on these sensitive aquatic resources.

Human activity at Candlestick Point following completion of construction would affect wildlife, including invertebrates, reptiles, amphibians, birds, and mammals. Potential adverse effects include disturbance of individuals (including nesting birds) in terrestrial, shoreline, and aquatic habitats due to movement by humans, domestic animals, and vehicles; depredation of native species by domestic animals; injury or mortality of individuals due to vehicular traffic; and other impacts. In addition, an increase in trash, particularly food waste, could potentially subsidize nuisance species, which in turn could increase predation on more sensitive wildlife species. However, as discussed in Impact BI-2, adverse effects of human disturbance and other operational factors would occur primarily to small numbers of regionally abundant species, and operational impacts would not substantially affect populations of these species. Impacts would be less than significant, and no mitigation is required.

Furthermore, for many of these common species, adverse effects of human disturbance on local (i.e., Project-wide) numbers would be offset by the benefits of habitat improvements incorporated into the Project's Draft Parks, Open Space, and Habitat Concept Plan (required by mitigation measure MM BI-7b). Thus, operational activities at Candlestick Point would benefit terrestrial biological resources.

Impact of Hunters Point Shipyard Phase II

Impact BI-16b **Implementation of the Project at HPS Phase II, including operation of the proposed marina, would not have a substantial adverse effect, either directly or through habitat modifications, on aquatic species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS or interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites. (Less than Significant) *[Criteria N.a and N.d.]***

Operation of the marina and marina-related activities (personal watercraft operations) would have the potential to disturb marine mammals and birds. The marine mammals most likely to be disturbed are locally foraging harbor seals. There are no known pupping sites or major haulout locations where animals would be subject to increased disturbance from vessel traffic from the Project. San Francisco Bay provides resting and foraging habitat for a variety of waterfowl migrating along the Pacific flyway. These birds often congregate into relatively large rafts of birds. Those rafts are subject to the disturbance from noise, size, speed, and wakes generated by vessel traffic. The common response to disturbance is for the birds to fly off the water surface and fly some distance away and land. Both the marina and marina-related (personal watercraft operations) activities would increase the disturbance to birds resting and foraging on Bay waters. However, out of a 300-slip marina, only a small percentage of the boats docked there are expected to be in use at any one time. Considering the size of the Bay, the number of boats currently on the bay at any one time, and the amount of disturbance currently generated by the existing boats on the Bay, the few

boats that at any one time are moving from the proposed marina into the Bay are not expected to generate substantial additional disturbance over current conditions. Consequently, they would not have substantial adverse effects on migrating or resting waterfowl.

Piers 1, 2, and 3 at the south side of HPS Phase II would be separated from the shore, but would remain in place. Those piers could provide resting, and potentially nesting, habitat for gulls, terns, and other marine-oriented species. Recreational use of the area would be limited to fishing from boats; however, the water is relatively shallow and not likely to support substantial populations of sportfish such that large amounts of angler (recreational fishermen) disturbance would be generated at any one time. Also, the existing piers are well above the water surface, separating resting birds from direct interaction with anglers. Therefore, recreational boating or fishing in this area would not be expected to substantially affect birds using or traveling to and from those piers. For these reasons, the operation of the marina and marina-related activities the marina would not have a substantial adverse effect on marine mammals and resting waterfowl.

Human activity at HPS Phase II following completion of construction would affect wildlife, including invertebrates, reptiles, amphibians, birds, and mammals, as described above for Candlestick Point. However, adverse effects of human disturbance and other operational factors would not substantially affect populations of these species. Impacts would be less than significant, and no mitigation is required.

Furthermore, for many of these common species, adverse effects of human disturbance on local (i.e., Project-wide) numbers would be offset by the benefits of habitat improvements incorporated into the Project's Draft Parks, Open Space, and Habitat Concept Plan (required by mitigation measure MM BI-7b). Thus, operational activities on HPS Phase II would benefit terrestrial biological resources.

Impact BI-17: Nesting American Peregrine Falcons

Impact of Candlestick Point

Impact BI-17a **Implementation of the Project at Candlestick Point would not have a substantial adverse effect, either directly or through habitat modifications, on nesting American peregrine falcons, identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (No Impact) *[Criterion N.a]***

No American peregrine falcons nests are found within Candlestick Point. No impact would occur, and no mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact BI-17b **Implementation of the Project at HPS Phase II would not have a substantial adverse effect, either directly or through habitat modifications, on nesting American peregrine falcons, identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. (No Impact) *[Criterion N.a]***

As previously discussed under Impact BI-6b, a resident pair of American peregrine falcons has been observed successfully nesting on the Re-gunning crane on Parcel D of HPS Phase II. The Project's operations would not result in substantial adverse effects to the falcons' nesting activities as the nesting

pair currently present has persisted, and nested successfully, at this site for several years even while remediation activities have been ongoing in the vicinity of the nest site. Many pairs of this species nest in high disturbance and heavily illuminated locations such as the towers in downtown San Francisco (i.e., the Pacific Gas and Electric Company's Headquarters) and the Bay Bridge (adjacent to construction activities). Operation activities of the Project would not result in substantial adverse effects on nesting American peregrine falcons. No impact would occur, and no mitigation is required.

Impact BI-18: Sensitive Aquatic Species, Mollusks, and Designated EFH

Impact of Candlestick Point

Impact BI-18a **Implementation of the Project at Candlestick Point would not have a substantial adverse effect, either directly or through habitat modifications, on aquatic species identified as a candidate, sensitive, or special-status in local or regional plans, policies, or regulations, or by the CDFG or USFWS, or have a substantial adverse effect on designated EFH, a sensitive natural community identified in local or regional plans, policies, and regulations or by the NMFS. (No Impact)** ***[Criteria N.a and N.b]***

Operational activities within Candlestick Point do not contain an in-water operational component and would not generate increases in turbidity or other impacts that could adversely affect species identified as a candidate, sensitive, or special-status, or designated EFH. Rather, the shoreline improvements would reduce erosion relative to existing conditions, thus reducing the potential for any re-suspension of sediments. No impact would occur, and no mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact BI-18b **Implementation of the marina in HPS Phase II would require routine maintenance dredging of the marina, which could remove habitat or generate substantial increases in turbidity within the marina, but would not have a substantial adverse effect, either directly or through habitat modifications, on species identified as a candidate, sensitive, or special-status in local or regional plans, policies, or regulations, or by the CDFG or USFWS, or have a substantial adverse effect on designated EFH, a sensitive natural community identified in local or regional plans, policies, and regulations or by the NMFS. (Less than Significant with Mitigation)** ***[Criteria N.a and N.b]***

Routine dredging of the marina could be required to maintain operational depth over the life of the Project. Dredging of marinas typically involves a clamshell excavator, which is used to physically remove sediments that are then transported off site for disposal. This method of sediment removal results in massive suspension of Bay mud. Those particles eventually settle out onto the seafloor and surrounding substrates. Up to several inches of new sediment deposition is possible. This would result in Project effects on sensitive species and EFH through two avenues.

The first is alteration of or removal of habitat, which occurs when this sediment settles out onto native oysters or spawning substrate for herring (there is no known eelgrass within the marina location). Oysters require hard substrates to attach to and are unable to move above layers of sediment as they are deposited.

Oysters are likely found on most hard substrates within the area and would settle onto the new breakwaters, piers, and floating dock system. Increased rates of sediment accumulation could decrease their survival. Pacific herring attach their eggs to had substrates and aquatic vegetation (docks, pilings, piers, eelgrass, etc). Sediment accumulation that would affect herring would only occur on relatively flat substrates (i.e., riprap). Because herring can spawn on vertical substrates (i.e., piers or breakwaters) and they can actively choose spawning habitats, the deposition of sediment within the marina would not result in a substantial reduction in available habitat.

The second avenue of potential impact could occur if the sediment plume disrupts behavior of fish managed under EFH regulations. These disturbances are expected to be temporary because fish can swim away from the plume and dredging operations. Because of this, maintenance dredging of the marina would have only a temporary impact on these species, and this is considered a less-than-significant impact. Pacific herring could spawn within the marina, but all dredging windows for the Bay do not allow dredging to occur during the spawning season, and, therefore, dredging would not impact spawning herring resource.

Implementation of mitigation measure MM BI-18b.1 would reduce the effects of marina maintenance dredging to less-than-significant levels by requiring compensatory mitigation for impacts to oysters and EFH that would be designed to avoid, minimize, and if avoidance is not feasible, restore oyster habitat and EFH. Mitigation measure MM BI-18b.2 would mandate the application of BMPs to control the distribution of sediments disturbed by the dredging activities. Consequently, implementation of both measures would reduce adverse effects of sedimentation associated with dredging to less-than-significant levels.

MM BI-18b.1 *Maintenance Dredging and Turbidity Minimization Measures for the Operation of the Marina. Maintenance dredging for the marina could remove or generate sediment plumes that could impact special-status species, their habitats, and Essential Fish Habitat (EFH). To minimize this effect, the following measures shall be implemented by the Project Applicant:*

1. *Conduct a detailed survey for native oysters in all suitable substrates within the marina, which includes the area between the land and breakwaters, after construction of the new breakwaters. This survey shall be conducted by a qualified oyster biologist at low tides that expose the maximum amount of substrate possible. Surveys can be conducted at any time of year, but late summer and early fall are optimal because newly settled oysters are detectable. This survey shall occur before any construction within the proposed marina location takes place to establish a baseline condition. If few or no oysters are observed on hard substrates that would remain in place after dredging, no further mitigation is required.*
2. *If oysters are found at densities at or above 90 oysters per square meter[837] on suitable oyster-settlement substrates that would be removed or in areas where dredging sediment could settle out onto the oysters, a detailed sediment plume modeling study of the proposed marina operation shall be conducted to determine if the operations and maintenance of the marina would generate a substantial plume of sediment. This model shall include the local bathymetry and sediment information, tidal data, and detailed marina information (number and types of boats, etc). The model shall be prepared by a qualified harbor engineer (as approved by the City/Agency) with direct experience in this type of work within San Francisco Bay, prior to issuance of any permits for the construction of features directly associated with the marina. A report documenting modeling*

[837] MACTEC Engineering and Consulting, Inc. 2008. *Oyster Point Marina Olympia Oyster Surveys Pre- and Post-Dredging February 2008, Oyster Point Marina, South San Francisco, California*. Prepared for PBS&J; Obernolte. 2009. Personal communication between MACTEC and PBS&J.

methods, input data, assumptions, results, and implications for increased rates of sedimentation shall be prepared and provided to NMFS during the USACE-directed Section 7 and EFH consultation for the marina. If the model demonstrates minimal sediment resuspension that would settle out before reaching sensitive habitats, no further mitigation is required.

3. *If the sediment plume reaches sensitive shoreline habitats (substrates that support native oysters), compensatory mitigation shall be provided by the Project Applicant at a ratio recommended by NMFS for the type of habitat adversely affected. The Project Applicant shall retain a qualified oyster biologist (as approved by the City/Agency) to develop an Oyster Restoration Plan that shall be reviewed and approved by the City/Agency. This Plan shall include site selection, substrate installation, and monitoring procedures, and include the following components (unless otherwise modified by NMFS):*

   > *A suitable site for installation of replacement substrate would be one with adequate daily tidal flow, a location that would not be affected by maintenance dredging or other routine marina maintenance activities, and one that is lacking in appropriate settlement substrate. A location outside of the new breakwaters or in association with any eelgrass mitigation sites would be appropriate.*

   > *Although oysters would settle on a variety of materials, the most appropriate for restoration purposes is oyster shell. This is typically installed by placing the shell into mesh bags that can then be placed in piles on the seafloor of the mitigation site. Enough shell shall be installed under the guidance of a qualified oyster biologist to make up for the loss attributable to the Project. Mitigation shall occur after construction of all in-water elements of the Project within HPS Phase II.*

   > *The restoration site shall be monitored on a regular basis by a qualified oyster biologist for a minimum of two years, or until success criteria are achieved if they are not achieved within two years. Monitoring shall involve routine checks (bi-monthly during the winter and monthly during the spring and summer) to evaluate settlement, growth, and survival on the mitigation site. Success shall be determined to have been achieved when settlement and survival rates for oysters are not statistically significantly different between the mitigation site and either populations being impacted (if data are available) or nearby established populations (i.e., Oyster Point Marina).*

MM BI-18b.2 *Implement BMPs to Reduce Impacts of Dredging To Water Quality. BMPs established in Appendix I of the Long-Term Management Strategy (LTMS) for management of disposal of dredge material in San Francisco Bay are designed specifically to minimize spread of contaminants Long-Term Management Strategy (LTMS) outside of dredge areas. All of these elements of the LTMS shall be applied to any proposed dredging or construction activities associated with the Project unless otherwise modified by the USACE, BCDC, or SFRWQCB in permit conditions associated with the proposed dredging activities associated with this Project (same as MM BI-19b.2).*

Impact BI-19: Contaminated Sediments during Operation

Impact of Candlestick Point

Impact BI-19a **Implementation of the Project at Candlestick Point would not result in impacts to aquatic organisms through the re-suspension of contaminated sediments. (No Impact) *[Criteria N.a and N.b]***

Operational activities within Candlestick Point do not contain an in-water operational component and would not result in the re-suspension of contaminated sediments that could have health consequences for

sensitive fish species and degrade EFH. Rather, the shoreline improvements would reduce erosion relative to existing conditions, thus reducing the potential for any re-suspension of contaminants. No impact would occur, and no mitigation is required.

Impact of Hunters Point Shipyard Phase II

Impact BI-19b **Implementation of the marina in HPS Phase II would not have a substantial adverse effect, either directly or through habitat modifications, on sensitive aquatic species, identified as candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS, or have a substantial adverse effect on designated EFH, a sensitive natural community identified in local or regional plans, policies, and regulations or by the CDFG or USFWS, or have a substantial effect on predators that prey on contaminated species or feed on contaminated substrates as a result of routine maintenance dredging or could generate routine increases in turbidity within the marina that would result in the re-suspension of contaminated sediments. (Less than Significant with Mitigation) *[Criteria N.a and N.b]***

Much of the seafloor within the Study Area is contaminated from decades of industrial use.[838] The primary contaminants are metals such as copper, lead, mercury, and polychlorinated biphenyl (PCBs), concentrations of which diminish with distance from the shoreline.[839] Routine dredging activities required to maintain operational depth of the marina could result in the suspension of contaminated sediments from the seafloor. Contaminants in these sediments may be taken up by aquatic organisms, either within the marina or in other areas to which contaminated sediments are carried by tides or currents. The uptake of contaminated food sources or exposure to elevated levels of toxins can reduce reproductive success, alter blood chemistry, suppress a fish's immune systems, and result in an increased risk of disease and mortality.[840,841] These effects may occur in aquatic organisms that take up contaminated substances directly, wildlife species (such as shorebirds) that forage in contaminated substrates, or predators that feed on prey that have taken up contaminants. Such impacts are potentially significant.

To reduce these impacts to less-than-significant levels, the following mitigation measures would be implemented.

MM BI-19b.1 *Work Windows to Reduce Maintenance Dredging Impacts to Fish during Operation of the Marina. According to the Long-Term Management Strategy (LTMS), dredging Projects that occur during the designated work windows do not need to consult with NMFS under the federal* Endangered Species

838 Barajas and Associates, Inc. 2008. Final Feasibility Study Report for Parcel F, Hunters Point Shipyard, San Francisco, California. Prepared for Base Realignment and Closure Program Management Office West.
839 Barajas and Associates, Inc. 2008. Final Feasibility Study Report for Parcel F, Hunters Point Shipyard, San Francisco, California. Prepared for Base Realignment and Closure Program Management Office West.

841 Landhal, J.T., L.L. Johnson, J.E. Stein, T.K. Collier, and U. Varanasi, 1997. Approaches for determining affects of pollution on fish populations in Puget Sound. *Transactions of the American Fisheries Society* 126: 519-535.

Act *(FESA).*[842] *The window in which dredging is allowed for the protection of steelhead in the central Bay is June 1 to November 30. The spawning season for the Pacific herring is March 1 to November 30.*[843] *Therefore, the window that shall be applied to minimize impacts to sensitive fish species is December 1 to February 28, upon consultation with NMFS.*

MM BI-19b.2 *Implement BMPs to Reduce Impacts of Dredging To Water Quality. BMPs established in Appendix I of the Long-Term Management Strategy (LTMS) are designed specifically to minimize spread of contaminants outside of dredge areas. All of these elements of the LTMS shall be applied to any proposed dredging or construction activities associated with the Project unless otherwise modified by the USACE, BCDC, or the San Francisco Bay Regional Water Quality Control Board in permit conditions associated with the proposed dredging activities associated with this Project (same as MM BI-18b.2).*

Implementation of mitigation measures MM BI-19b.1 and MM BI-19b.2 would reduce contamination associated with dredging to less-than-significant levels by (1) reducing the effects of increased contamination resulting from routine maintenance dredging by requiring that dredging occur during established work windows when sensitive fish species are less likely to be present, and (2) mandating application of BMPs to control the distribution of sediments disturbed by the dredging activities. Consequently, implementation of these mitigation measures would reduce potential adverse effects to less-than-significant levels.

Impact BI-20: Wildlife Movement

Impact of Candlestick Point

Impact BI-20a **Implementation of the Project at Candlestick Point would not interfere substantially with the movement of resident or migratory bird species by increasing collision hazards and the amount of artificial lighting. (Less than Significant with Mitigation) *[Criterion N.d]***

The Project would be located along the Pacific Flyway for migratory birds. Migrating birds, such as songbirds, can be affected by human-built structures because of their propensity to migrate at night, their low flight altitudes, and their tendency to be disoriented by artificial light, making them vulnerable to collision with obstructions.[844] In addition, birds migrating at night are strongly attracted to sources of artificial light, particularly during periods of inclement weather.[845] Exposure to a light field at night can cause alteration of a straight flight path, and the change in flight path would keep the bird near the light source longer than if the flight path remained straight.[846] Brightly lit buildings can confuse migrating birds, trapping them in the bright light, which they are reluctant to fly out of, until they are exhausted or collide

[845] Ibid.
[846] Ibid.

with a building.[847] Confused by artificial lights, blinded by the weather, and unable to see glass, large numbers of birds have been documented being injured or killed by colliding with buildings in eastern and midwestern North America.[848] Summaries of documented mortality from bird collisions have almost invariably focused on mortality in those regions, however, and large-scale mortality at buildings on the West Coast has not been reported.[849,850]

At Candlestick Point, residential towers would range from 200 to 420 feet in height and the majority of local bird movement would be expected to be along the shoreline of San Francisco Bay, especially for shorebirds, as they move from foraging habitat to perching or roosting habitats in response to changes in the tide. Because the existing structures are relatively low (i.e., Candlestick Park stadium), the risk of bird strikes under existing conditions is expected to be minimal. New buildings from 200 to 420 feet in height would constitute a substantial increase in obstacles within flight paths when compared to existing conditions. The Project would create bird strike hazards at elevations that do not currently exist. With structures 400 feet tall or taller and windy, often foggy conditions found along San Francisco Bay, the risk of collision for birds would increase. Therefore, the Project could result in the creation of a new strike hazard for migrating birds that could result in loss of substantial numbers of birds over the life of the Project. Additionally, operating effects associated with the lighting of the towers can alter the flight patterns of migratory birds and potentially increase bird strike collisions with the tall buildings.

Although large-scale injury or mortality of birds due to collisions with buildings has not been reported from the West Coast, there is some potential for such mortality to occur in the absence of mitigation measures. Because of these potential effects, the Project is considered to have a potentially significant impact to migratory birds.

To reduce these impacts the following mitigation measures would be implemented.

MM BI-20a.1 *Lighting Measures to Reduce Impacts to Birds. During design of any building greater than 100 feet tall, the Project Applicant and architect shall consult with a qualified biologist experienced with bird strikes and building/lighting design issues (as approved by the City/Agency) to identify lighting-related measures to minimize the effects of the building's lighting on birds. Such measures, which may include the following and/or other measures, will be incorporated into the building's design and operation.*

- *Use strobe or flashing lights in place of continuously burning lights for obstruction lighting. Use flashing white lights rather than continuous light, red light, or rotating beams.*
- *Install shields onto light sources not necessary for air traffic to direct light towards the ground.*
- *Extinguish all exterior lighting (i.e., rooftop floods, perimeter spots) not required for public safety.*
- *When interior or exterior lights must be left on at night, the operator of the buildings shall examine and adopt alternatives to bright, all-night, floor-wide lighting, which may include:*
  - *Installing motion-sensitive lighting.*

- > *Using desk lamps and task lighting.*
- > *Reprogramming timers.*
- > *Use of lower-intensity lighting.*

- *Windows or window treatments that reduce transmission of light out of the building will be implemented to the extent feasible.*
- *Educational materials will be provided to building occupants encouraging them to minimize light transmission from windows, especially during peak spring and fall migratory periods, by turning off unnecessary lighting and/or closing drapes and blinds at night.*
- *A report of the lighting alternatives considered and adopted shall be provided to the City/Agency for review and approval prior to construction. The City/Agency shall ensure that lighting-related measures to reduce the risk of bird collisions have been incorporated into the design of such buildings to the extent practicable.*

MM BI-20a.2 *Building Design Measures to Minimize Bird Strike Risk. During design of any building greater than 100 feet tall, the Project Applicant and architect will consult with a qualified biologist experienced with bird strikes and building/lighting design issues (as approved by the City/Agency) to identify measures related to the external appearance of the building to minimize the risk of bird strikes. Such measures, which may include the following and/or other measures, will be incorporated into the building's design.*

- *Use non-reflective tinted glass.*
- *Use window films to make windows visible to birds from the outside.*
- *Use external surfaces/designs that "break up" reflective surfaces.*
- *Place bird attractants, such as bird feeders and baths, at least 3 feet and preferably 30 feet or more from windows in order to reduce collision mortality.*
- *A report of the design measures considered and adopted shall be provided to the City/Agency for review and approval prior to construction. The City/Agency shall ensure that building design-related measures to reduce the risk of bird collisions have been incorporated to the extent practicable.*

Measures such as these have been recommended by a number of authors and organizations to reduce the potential for avian collisions with buildings.[851,852,853,854,855,856] As discussed by Klem, "there are many solutions that effectively reduce or eliminate bird strikes" at buildings,[857] and mitigation measures MM BI-20a.1 and MM BI-20a.2 would reduce the effects of operational activities related to tall structures and increased lighting to birds to less-than-significant levels by incorporating these solutions. Specifically, these measures would reduce the incidence of bird strikes by requiring operational methods to reduce the effects of artificial lighting; making the structure (especially the glass surfaces) more visible from the outside with the use of external window coverings; and creating non-reflective or interference zones on or inside the glass. These measures

are promoted in eastern and midwestern cities such as Toronto, Chicago, and New York City where avian collisions with buildings have been much better documented than on the West Coast, and implementation of these mitigation measures would reduce potential adverse effects to less-than-significant levels.

Impact of Hunters Point Shipyard Phase II

Impact BI-20b **Implementation of the Project at HPS Phase II would not interfere substantially with the movement of resident or migratory bird species by increasing collision hazards and the amount of artificial lighting. (Less than Significant with Mitigation) *[Criterion N.d]***

Within HPS Phase II, the towers would range from 240 to 350 feet in height, and the 49ers Stadium would be up to 156 feet in height with the top of the stadium light towers at 192 feet. Migrating birds such as songbirds can be affected by human-built structures because of their propensity to migrate at night, their low flight altitudes, and their tendency to be disoriented by artificial light, making them vulnerable to collision with obstructions. Both tall structures and residential windows provide collision hazards to migrating birds. A majority of bird strikes occur when birds do not recognize windows on buildings. Thus, operation of the towers and stadium would pose collision hazards to migratory birds as effects associated with the lighting of the towers can alter the flight patterns of migratory birds and substantially increase bird strike collisions with the structures. As discussed under Impact BI-20a, large-scale avian injury or mortality due to bird strikes has not been documented at buildings on the West Coast as it has in eastern and midwestern North America. However, due to the potential for bird strikes at tall buildings on HPS Phase II, this would be a potentially significant impact.

Implementation of mitigation measures MM BI-20a.1 and MM BI-20a.2 would reduce the effects of operational activities related to tall structures and increased lighting to migrating birds to less-than-significant levels by incorporating design features that would help minimize bird strike, including using operation methods to reduce the effects of artificial lighting; making the structure, especially the glass surfaces, more visible from the outside with the use of external window coverings; and the creation of non-reflective or interference zones on or inside the glass. Consequently, implementation of these mitigation measures would reduce this impact to a less-than-significant level.

Impact BI-21: Local Plans and Policies

Impact of Candlestick Point

Impact BI-21a **Implementation of the Project at Candlestick Point would not conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance. (Less than Significant With Mitigation) *[Criterion N.e]***

As discussed in the consistency analysis for local policies in the Regulatory discussion above, operation of Candlestick Point would be consistent with the biological resources protection policies of the *City of San Francisco General Plan*. In addition, the City has adopted an Urban Forestry Ordinance and Section 143 of the Planning Code to protect trees as a significant resource to the community, and as discussed in Impact BI-14a, the Project's construction-related effects would comply with the Urban Forestry Ordinance to the extent applicable and, with mitigation measure MM BI-14a, would ensure that the Project is

constructed in a manner consistent with policies of the Urban Forestry Ordinance and *Planning Code* Section 143. Consequently, the operation of Candlestick Point would not conflict with any local policies or ordinances protecting biological resources, and the impact would be less than significant.

Impact of Hunters Point Shipyard Phase II

Impact BI-21b **Implementation of the Project at HPS Phase II would not conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance. (Less than Significant With Mitigation) *[Criterion N.e]***

As discussed in the consistency analysis for local policies in the Regulatory discussion above, operation of HPS Phase II would be consistent with the biological resources protection policies of the *City of San Francisco General Plan*. Further, as discussed in Impact BI-14b, with implementation of mitigation measure MM BI-14a, the Project's construction-related effects would be consistent with the policies set forth in the City's Urban Forestry Ordinance and policies reflected in Section 143 of the Planning Code for the protection of trees. Consequently, the operation of HPS Phase II would not conflict with any local policies or ordinances protecting biological resources, and the impact would be less than significant.

Project Impacts

The impact discussion below addresses the impacts of the overall Project, which is the combined development and operation of Candlestick Point and HPS Phase II, including the Yosemite Slough bridge.

Impact BI-22: Special-Status and/or Legally Protected Species

Impact BI-22 **Implementation of the Project would not have a substantial adverse effect, either directly or through habitat modifications, on species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, by the CDFG, USFWS, or NMFS. (Less than Significant with Mitigation) *[Criterion N.a]***

The Project would involve removal and/or modification of areas that have the potential to contain special-status species, including: seven potentially breeding avian species, one bat species, and four fish species (green sturgeon, Chinook, steelhead, and longfin smelt) (refer to Table III.N-5). The Project also has the potential to affect designated critical habitat of the green sturgeon and thus, directly impact threatened and/or endangered species through habitat conversion or unauthorized take. In addition, Project activities would occur within habitats of locally rare or sensitive species such as Pacific herring and Olympia oysters, as well as avian species protected by the MBTA and *California Fish and Game Code*.

Implementation of ecological Project design features described in the Draft Parks, Open Space, and Habitat Concept Plan (required by mitigation measure MM BI-7b) would result in multiple measures to avoid, limit, and mitigate for impacts to special-status and legally protected species. Specifically, the Project design components would remove invasive species; restore, preserve, and enhance wetland, aquatic and grassland habitats; create stormwater treatment wetlands; revegetate the site with extensive planting of trees and shrubs; increase the vegetative cover for foraging and dispersing animals; and maintain and enhance habitat connectivity along the shoreline.

Mitigation measures MM BI-5b.1 through MM BI-5b.4 would reduce the effects on eelgrass, and the sensitive or special-status fish species that could occupy these areas by surveying for and avoiding this habitat. For areas that cannot be avoided, the Project Applicant would implement a comprehensive eelgrass mitigation plan that would replace at a minimum ratio of 3:1 (i.e., 3 new acres of eelgrass to 1 removed acre) the impacted areas of eelgrass and monitor them for success over sequential years, thus replacing impacted habitat and increasing its abundance regionally. Residual adverse effects would be less than significant with this mitigation.

Mitigation measures MM BI-6a.1, MM BI-6a.2, and MM BI-6b would require surveys for special-status and nesting avian species and implement impact-avoidance measures such as construction buffers to ensure that the loss or take of these species would not occur. Potential impacts to burrowing owls would be mitigated through the conservation of lands as detailed in the *California Burrowing Owl Consortium's April 1995 Burrowing Owl Survey Protocol and Mitigation Guidelines*, and Project-related open space preservation. Residual adverse effects would be less than significant with this mitigation.

Impacts to foraging raptors would be beneficial due to the removal of invasive plants and improvement of existing parkland through the restoration and management of native-dominated grassland. Only 5.13 acres of the lands impacted on Candlestick Point provide non-native grassland habitat that serves as foraging habitat for raptors. In addition, the Project would mitigate impacts to 43 acres of non-native grassland that provides raptor foraging habitat on HPS Phase II by restoring an equivalent amount of higher-quality native-dominated grassland specifically managed for grassland-associated species (see mitigation measure MM BI-7b). These areas would provide high-quality foraging habitat, and a net increase in the quality of raptor foraging habitat would result.

Mitigation measure MM BI-9b would reduce the effects of pile driving-related activities to fish and marine mammals by recommending the type of piles to use to minimize sound impacts; providing for an alternative method of installation to minimize sound impacts; requiring installation during an agency-approved construction window when fish are least likely to be present to avoid the bulk of potential impacts; and requiring a construction monitor to ensure compliance with all measures, including sound monitoring. Residual adverse effects would be less than significant with this mitigation.

Development of the Project would require in-water work associated with the shoreline treatments. All work would occur in relatively shallow water areas that are unlikely to support foraging special-status fish. Still, the NMFS has considered the entire Bay in the site vicinity to be designated critical habitat for the green sturgeon and Central California Coast steelhead, and there is some possibility that individuals of these species, as well as other special-status fish such as Chinook salmon and longfin smelt, could be impacted by shoreline construction activities. Compensatory mitigation for Project impacts to aquatic habitat would be provided as described by mitigation measure MM BI-4a.1, and mitigation measure MM BI-4a.2 would be implemented to minimize impacts to wetlands, aquatic habitats, and water quality during construction. Implementation of these measures would reduce potential adverse effects on special-status fish species to less-than-significant levels. Further, a net increase of approximately 8 acres of new aquatic habitat as a result of removal of fill and structures would more than offset the loss of open water habitat.

Impacts to western red bats would be less than significant as, although the removal of large trees could lead to disturbance and mortality of a very limited number of individuals of this species, the loss or

disturbance would not represent a substantial adverse effect as it would not substantially reduce the habitat of this species, cause its population to drop below self-sustaining levels, or reduce its range. In addition, implementation of the Project's ecological design features, as described in the Draft Parks, Open Space, and Habitat Concept Plan, would result in increased habitat for this species.

Impacts to native oysters and EFH would be less than significant as removed hard structures would be replaced with approximately equal amounts of suitable habitat along the shoreline or the new breakwater. Implementation of mitigation measure MM BI-18b.1 would reduce the effects of marina operational activities to less-than-significant by (1) determining the distribution of oyster populations within the new marina area, and (2) preparing a modeling study of potential sediment plume generation and assessing the potential for that plume to reach oysters, and using that model to guide site-specific mitigation for sedimentation impacts to oysters that would be designed to avoid, minimize, and if avoidance is not feasible, restore oyster habitat. Implementation of mitigation measure MM BI-18b.2 would mandate the application of BMPs to control the distribution of sediments disturbed by the dredging activities to reduce water quality impacts to the species. Residual adverse effects would be less than significant with implementation of this mitigation measure.

The Project, with implementation of the above identified mitigation measures and ecological design features, would not have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS. Potential adverse effects would be reduced to less-than-significant levels.

Impact BI-23: Sensitive Habitats

Impact BI-23 **Implementation of the Project would not have a substantial adverse effect on sensitive natural communities identified in local or regional plans, policies, or regulations by the CDFG, USFWS, or NMFS. (Less than Significant with Mitigation)** ***[Criterion N.b]***

No riparian habitat occupies the Study Area and the only sensitive habitats other than wetlands and aquatic habitats (discussed in Impact BI-24) are eelgrass and areas designated as EFH.

A small area of eelgrass was reported along the north shore of the South Basin directly across from Candlestick Point and a second area was identified east of the northern end of Earl Street. Together these areas make up approximately 1.99 acres of this habitat Permanent removal of this habitat or substantial loss of productivity, such that it would no longer be ecologically functional, would result in the loss of a sensitive natural community, which would be a substantial adverse effect.

The Bay in the Project vicinity has been designated EFH for the Pacific Coast Salmon Plan, Coast Pelagics Fishery Management Plan, and Pacific Groundfish Fishery Management Plan. Installation of shoreline treatments that require modification of the substrate within the Bay would be considered to result in changes to designated EFH. Installation of shoreline treatments its modification to EFH (i.e., installation of rock fill material to buttress existing bulkheads) would be considered a substantial adverse effect. To reduce these potential construction-related impacts to less-than-significant levels, mitigation measures MM BI-12a.1, MM BI-12a.2, MM BI-12b.1, and MM BI-12b.2 would be implemented. Implementation of mitigation measure MM BI-18b.1 would reduce the effects of marina operational activities to EFH by

(1) determining the distribution of oyster populations within the new marina area, and (2) preparing a modeling study of potential sediment plume generation and assessing the potential for that plume to reach oysters, and using that model to guide site-specific mitigation for sedimentation impacts to EFH that would be designed to avoid, minimize, and if avoidance is not feasible, restore oyster habitat. Implementation of mitigation measure MM BI-18b.2 would mandate the application of BMPs to control the distribution of sediments disturbed by the dredging activities to reduce water quality impacts to EFH.

Mitigation measures MM BI-5b.1 through MM BI-5b.4 would reduce potential Project effects on eelgrass by requiring surveys for and avoidance of this habitat. For areas than cannot be avoided, the Project Applicant would implement a comprehensive eelgrass mitigation plan that would replace at a minimum ratio of 3:1 (i.e., 3 new acres of eelgrass to 1 removed acre) the impacted areas of eelgrass and monitor them for success over a 5-year period, thus, replacing impacted habitat and increasing its abundance regionally. Residual impacts would be less than significant with implementation of this mitigation measure. Mitigation measures MM BI-19b.1 and MM BI-19b.2 would reduce dredging and contamination impacts to EFH to less-than-significant levels by (1) reducing the effects of increased contamination resulting from routine maintenance dredging by requiring that dredging occur during established work windows when sensitive fish species are less likely to be present, and (2) mandating application of BMPs to control the distribution of sediments disturbed by the dredging activities.

With implementation of the identified mitigation measures, the Project's potential adverse effects to sensitive natural communities identified in local or regional plans, policies, regulations or by the CDFG, NMFS, or USFWS would be reduced to a less–than-significant level.

Impact BI-24: Wetlands and Jurisdictional Waters

Impact BI-24 **Implementation of the Project would not have a substantial adverse effect on federally protected wetlands and other waters as defined by Section 404 of the *Clean Water Act* (including, but not limited to, marsh, coastal, etc.) through direct removal, filling, hydrological interruption, or other means. (Less than Significant with Mitigation) *[Criterion N.c]***

Table III.N-4 depicts on-site and off-site impact acreages resulting from site grading, materials laydown, facilities construction, vegetation removal, and installation of shoreline treatments for Candlestick Point, HPS Phase II, and Yosemite Slough bridge. Project implementation would permanently impact 0.74 acre of wetlands; including 0.17 acre of freshwater wetland, 0.42 acre of tidal salt marsh and 0.15 acre of non-tidal salt marsh. In addition, Project implementation would permanently impact 24.97 acres of Section 404 other waters. The Project would temporarily impact 0.01 acre of jurisdictional wetlands and 2.76 acres of Section 404 other waters. Temporary impacts are short term because, after construction, any areas disturbed would be restored to pre-construction conditions that would have equal or greater habitat functions and values. Approximately 3-4 acres of impacts to jurisdictional wetlands and other waters would result from the placement of marsh soils and other materials along portions of the shorelines of Candlestick Point and the southern edge of HPS Phase II to promote the development of a strip of tidal wetlands along the shoreline. Although such impacts are considered permanent, since they would modify these areas relative to their existing condition, these impacts are considered self-mitigating in that they would enhance habitat conditions relative to both the existing shoreline and, along the southern edge of HPS, the riprap

revetment that is expected to be constructed by the Navy following completion of remediation. Further, a net increase of approximately 8.09 acres of open water would occur as a result of the Project.

Of the 28.48 acres of total impacts to jurisdictional wetlands and other waters of the US that would occur as a result of the Project, jurisdictional areas that would be completely lost (i.e., converted to non-jurisdictional habitats) total only approximately 5.26 acres. This loss of habitat would occur primarily due to construction of the abutments of the Yosemite Slough bridge, along the northern approach road to the bridge, where a freshwater wetland is located in the west-central part of the site, and where construction of new breakwaters, a floating dock, and a gangway would occur at the marina. Approximately 12 acres would result from fill placed for drydock repairs, buttressing required to support existing pier walls and bulkheads, or other shoreline improvements.

The Project also includes the removal of some shoreline structures (i.e., piers and/or bulkheads) and fill material that are currently present in jurisdictional areas. For example, portions of the Re-gunning pier and edges of bulkheads along much of the eastern part of HPS Phase II would be removed to create new open-water habitat. Although these areas are considered permanently impacted for the purposes of this impact assessment, since some fill would be placed along the new shoreline of these bulkheads for stabilization purposes, removal of structures and fill would restore approximately 8 acres of aquatic habitat. Considering that marsh restoration along the southern edge of HPS and portions of Candlestick Point is responsible for approximately 3 to 4 acres of impacts, approximately 11 to 12 acres of the total 28.48 acres of impacts to jurisdictional areas on the Project site would result from activities that would enhance ecological conditions along the shoreline.

Direct removal, placement of fill into, or hydrological interruption of federally or state-protected wetlands defined that would result in a net loss of these areas would be considered a significant impact. Conformance with the CWA (via Sections 404 and 401 certification), Section 10 of the *Rivers and Harbors Act*, BCDC permitting requirements, and the NPDES regulations would ensure, among other things, that there is no net loss of wetlands and that water quality is maintained. Mitigation measures MM BI-4a.1 and MM BI-4a.2 would reduce the effects of construction-related activities to wetlands and other waters by mitigating for the temporary and permanent loss of the wetlands and jurisdictional waters through avoidance of impacts, requiring compensatory mitigation (i.e., creation, preservation, and/or restoration), obtaining permits from the USACE, SFRWQCB, and BCDC that are designed to protect wetlands and jurisdictional waters, and implementing construction Best Management Practices to reduce and/or prevent impacts to waters of the United States, including wetlands and navigable waters. With implementation of mitigation measures MM BI-4a.1 and MM BI-4a.2, potential adverse effects of the Project to federally protected wetlands and other waters as defined by Section 404 of the *Clean Water Act* would be reduced to a less-than-significant level.

Impact BI-25: Wildlife Movement

Impact BI-25 **Implementation of the Project would not interfere substantially with the movement of native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery site. (Less than Significant with Mitigation)** ***[Criterion N.d]***

The Study Area is surrounded by open water and urban development and no major drainages, canyon bottoms, ridgetops, rivers, creeks or areas that provide substantial movement corridors or migratory pathways occur within the Study Area.

The majority of the bird species observed in the Study Area were terrestrial species, followed by shorebirds, waterfowl, gulls and terns, and raptors (in descending order). Very few Neotropical and other long-distance migrant songbirds were recorded during the survey. However, implementation of the Project would place new residential towers and a stadium with light towers along a portion of the San Francisco Bay shoreline. The increase in strike hazards from the tall buildings would be considered a potentially significant impact to migratory birds. The lighted stadium could also affect birds migrating at night, since lighting can disorient migrating birds, although lighting from the new stadium is unlikely to result in a substantially greater effect than lighting from the existing stadium on Candlestick Point.

With respect to aquatic species, the Project does not contain any substantial migratory fish pathways such as anadromous fish streams, although migratory fish do move through the open water and, possibly, into Yosemite Slough as they do throughout all of the San Francisco Bay estuary. The Project would not substantially interrupt any fish movements that currently occur. However, construction of breakwaters and other shoreline treatments in HPS Phase II would occur near eelgrass beds, which could directly or indirectly impact them such that productivity and survival of these habitats would be substantially reduced. Eelgrass communities are considered important aquatic nursery sites as they serve as a haven for numerous aquatic species. Elimination of these important nursery areas would be considered a significant impact due to the ecological importance of these habitats to aquatic species. Mitigation measures MM BI-5b.1 through MM BI-5b.4 would reduce the effects on eelgrass by requiring survevs for and avoidance of this habitat. For areas than cannot be avoided, the applicant would implement a comprehensive eelgrass mitigation plan that would replace at a minimum ratio of 3:1 (i.e., 3 new acres of eelgrass to 1 removed acre) for impacted areas of eelgrass and monitor them for success over sequential years; thus, replacing impacted habitat and increasing its abundance regionally. Mitigation measures MM BI-20a.1 and MM BI-20a.2 would reduce the effects of operational activities related to tall structures and increased lighting to birds to less-than-significant levels by incorporating design features that would help minimize bird strikes, including using operational methods to reduce the effects of new lighting towers and design measures to make the exteriors of buildings more readily visible to birds.

With implementation of the identified mitigation measures, impacts of the Project would be reduced to a less-than-significant level as the Project would not interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites.

Impact BI-26: Local Plans and Policies

Impact BI-26 **Implementation of the Project would not conflict with local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance. (Less than Significant with Mitigation)*[Criterion N.e]***

As discussed previously, the Project would be consistent with the biological resources protection policies of the *City of San Francisco General Plan*. However, construction activities associated with the Project could result in disturbance or loss of trees within DPW jurisdiction. These trees would be subject to the requirements of the *Public Works Code*, which specifies a process for gaining approval to remove trees, and requires the protection of trees during construction activities. Trees approved for removal must be replaced in accordance with DPW requirements. Compliance with the City's Street Tree Ordinance will reduce impacts to trees within DPW jurisdiction to a less-than-significant level.

The removal of trees located outside of DPW jurisdiction is not subject to regulation by the *Public Works Code*. However, the removal of large numbers of trees, particularly trees that meet the size definition of significant trees, without replacement of trees, could result in conflicts with policies articulated in the City's Urban Forestry Ordinance. The ordinance identifies trees as important to the urban environment because they improve air quality and wildlife habitat, contribute to psychological well-being and the aesthetic environment, and decrease noise. The City's *Planning Code* Section 143 embodies similar policies by requiring the planting of certain quantities of street trees when constructing new development in certain areas of the City. The Planning Code does not automatically apply in redevelopment areas, so the development that does not include planting of street trees would conflict with the policy goals of Section 143.

Mitigation measure MM BI-14a would encourage the preservation of street trees and trees that are large enough to meet the size specification of significant trees in the *Public Works Code*, and would require the replacement of large trees that are removed. Further, it would require the planting of street trees consistent with the intent of the *Planning Code* Section 143. In addition, mitigation measure MM BI-7b includes the planting of approximately 10,000 net new trees at the Project site and in the community. The planting of an estimated 10,000 net new trees would increase the number of trees in the Study Area considerably, increase canopy cover, and promote a healthy and sustainable urban forest. With implementation of mitigation measures MM BI-14a and MM BI-7b, the Project would not result in a conflict with City policies designed to protect urban streetscape through the planting of street trees, and impacts would be less than significant.

The Draft Parks, Open Space, and Habitat Concept Plan (required by mitigation measure MM BI-7b) includes the planting of an estimated 10,000 net new trees at the Project site and in the community, avoids removal of native trees where possible, and establishes new parkland and open space that would include a predominance of native species. Consequently, the Project would not conflict with any local policies or ordinances protecting biological resources, and overall impacts of the Project are expected to be beneficial.

Cumulative Impacts

The geographic context for the analysis of cumulative impacts to biological resources varies, depending on the specific threshold being analyzed. The appropriate context is described for each subsection. The past and present development is generally described in the Setting section of this chapter but may also include existing development around the shoreline of the San Francisco Bay, as described in the applicable

geographic context for each criterion (refer to discussion below). Reasonably foreseeable development would include those cumulative projects that could be developed in the specified geographic area, as well as planned and in-process wetland restoration plans within the Bay area.[858] The cumulative analysis in this section is grouped by Criteria N.a through N.e identified earlier in this chapter. Criteria N.a and N.b are analyzed together. Criteria N.f and N.e. are not analyzed, as the Project would have no impact on any Habitat Conservation Plan and a beneficial impact to local plans and policies.

Effects on Candidate, Sensitive, or Special-Status Species, Riparian Habitat. or other Sensitive Natural Communities (Criteria N.a. and N.b)

The geographic context for the cumulative analysis of effects on sensitive species and sensitive natural communities is the San Francisco Bay shoreline (Region), defined north to south by the land mass and by the Carquinez Bridge on the east where I-80 crosses the Sacramento-San Joaquin Rivers at Vallejo, upstream of San Pablo Bay, and the Golden Gate Bridge on the west. This regional context contains some or all of the species and habitats identified in the Study Area. Past and present development is described in the Setting section of this chapter, along with other existing development on or adjacent to the Bay shoreline. Reasonably foreseeable development would consist of projects proposed or under construction along the shoreline of the San Francisco Bay that could affect the identified species, habitat, or sensitive natural community.

In general, cumulative projects within the Bay would include, but not be limited to new development, marinas, shoreline protection projects, flood protection projects in light of anticipated sea level rise, transportation projects, and restoration projects. These projects could involve removal and/or modification of areas that have the potential to contain special-status species and sensitive natural communities (wetlands are discussed in a separate impacts statement below). As development in the Region continues, habitat for and individuals of sensitive wildlife species native to the Region, including those species listed under federal and state ESAs and those individuals identified by state and federal resources agencies as species of concern, fully protected, or sensitive, would be lost through conversion of habitat to urbanized environment. Although more mobile species might be able to survive these changes in their environment by moving to new areas, less mobile species could simply be locally extirpated. With continued conversion of natural habitat to human use, the availability and accessibility of remaining natural habitats in this ecosystem would dwindle and those remaining natural areas may not able to support additional plant or animal populations above their current carrying capacities. Thus, the conversion of plant and wildlife habitat on a Regional level would, therefore, result in a significant regional cumulative impact on special-status species and their habitats.

The terrestrial habitats within the Project site are of low quality to terrestrial wildlife species, consisting of urbanized areas, non-native annual grassland, and landscaped areas/ornamental plants. However, some areas of moderate to high-quality habitat such as salt marsh, mud flats, and seasonal freshwater wetland, which could support special-status species, would also be impacted. The Project would also affect designated critical habitat for green sturgeon and Central California Coast steelhead, and could possibly affect individuals of these and other listed fish species. Thus, the Project could directly or indirectly impact

[858] South Bay Salt Pond Restoration Project Final Environmental Impact Statement/Environmental Impact Report. Report December 2007.

threatened and/or endangered species. Lastly, Project activities could occur within habitats of locally rare or sensitive species such as Pacific herring spawning habitat, eelgrass, Olympia oyster beds, and areas designated as EFH. Consequently, without mitigation the Project would contribute to a loss of regional biological resources through the incremental conversion of habitat for special-status species to human use.

The Project may be required to participate in mitigation plans approved by state and federal resource agencies (i.e., for green sturgeon, Central California Coast steelhead and possibly Chinook salmon and longfin smelt), which would replace lost habitat and preserve contiguous areas of habitat for these species. The Project would also implement ecological design features and mitigation measures specifically designed to avoid, reduce, or mitigate impacts to special-status/sensitive species and their habitat and reduce the Project's contribution to the cumulative loss of these species and their habitats.

Implementation of the two ecological Project design features, as described in the Draft Parks, Open Space, and Habitat Concept Plan required by mitigation measure MM BI-7b, would result in multiple measures to avoid, limit, and mitigate impacts to special-status and legally protected species. Mitigation measures MM BI-4a.1 and MM BI-4a.2 would reduce the effects on wetlands and aquatic habitats.

Mitigation measures MM BI-5b.1 through MM BI-5b.4 would reduce the effects on eelgrass, and the sensitive or special-status fish species that could occupy these areas by surveying for and avoiding this habitat and replacing, at a minimum ratio of 3:1 (i.e., 3 new acres of eelgrass to 1 removed acre), the impacted areas of eelgrass that cannot be avoided. Mitigation measures MM BI-6a.1 MM BI-6a.2, and MM BI-6b would require surveys for special-status and nesting avian species and implement impact-avoidance measures such as construction buffers to ensure that the loss or take of these species would not occur. Potential impacts to burrowing owls would be mitigated through the conservation of lands as detailed in the *California Burrowing Owl Consortium's April 1995 Burrowing Owl Survey Protocol and Mitigation Guidelines*, and Project-related open space preservation. Impacts to foraging raptors would be beneficial due to the Project's ecological enhancements as described in the Draft Parks, Open Space, and Habitat Concept Plan (i.e., removal of invasive plants and improvement of existing parkland through the restoration and management of native-dominated grasslands), and the requirements specified in mitigation measure MM BI-7b. Only 5.13 acres of the lands impacted on Candlestick Point provide non-native grassland habitat that serves as foraging habitat for raptors. In addition, the Project would mitigate impacts to 43 acres of non-native grassland that provides raptor foraging habitat on HPS Phase II by restoring an equivalent amount of higher-quality native-dominated grassland specifically managed for grassland-associated species. These areas would represent high-quality foraging habitat and would result in a net increase in the quality of raptor foraging habitat. The Project would impact designated green sturgeon and Central California Coast steelhead critical habitat. However, compensatory mitigation for impacts to aquatic habitat, which include habitat used by green sturgeon and Central California Coast steelhead, would be provided as described by mitigation measure MM BI-4a.1, mitigating impacts to proposed green sturgeon critical habitat and designated Central California Coast steelhead to less-than-significant levels. In addition, the Project would create approximately 8 acres of new aquatic habitat throughout the removal of structures and fill from aquatic habitats in the Study Area. The Bay in the Project vicinity has been designated EFH for the Pacific Coast Salmon Plan, Coast Pelagics Fishery Management Plan, and Pacific Groundfish Fishery Management Plan. Installation of shoreline treatments that require modification of the substrate within the Bay would be considered a substantial adverse effect on designated EFH. Any loss of

EFH that would result from construction activities would be mitigated via the compensatory mitigation for impacts to jurisdictional waters (mitigation measure MM BI-4a.1), and mitigation measures MM BI-4a.2, MM BI-12a.1, MM BI-12a.2, MM BI-12b.1, and MM BI-12b.2 would also reduce or minimize potential adverse effects to EFH.

Consequently, with implementation of the proposed mitigation and ecological Project components the Project would mitigate any contributions to significant cumulative impact to candidate, sensitive, or special-status species, riparian habitat, or other sensitive natural communities. The Project would thus not make a cumulatively considerable contribution to a regionally significant cumulative impact.

Effects on Federally Protected Wetlands and Jurisdictional Waters (Criterion N.c)

The geographic context for the cumulative analysis of effects on wetlands or navigable waters is the San Francisco Bay shoreline and its adjacent wetlands, defined north to south by the land mass and by the Carquinez Bridge on the east where I-80 crosses the Sacramento-San Joaquin Rivers at Vallejo, upstream of San Pablo Bay, and the Golden Gate Bridge on the west. Past and present development is described in the Setting section of this chapter, along with other existing development on or adjacent to the Bay shoreline. Reasonably foreseeable development would consist of projects proposed or under construction

- along the shoreline of the San Francisco Bay, including the Yosemite Slough Restoration Project, that could affect federally protected wetlands or jurisdictional waters, either adversely (i.e., development projects) or beneficially (i.e., restoration projects). Permanent impacts are those that would remove wetlands or jurisdictional waters and not replace them in the exact same location. Temporary impacts are short term because, after construction, any areas disturbed would be restored to the previous condition.

More than 90 percent of historic tidal wetlands in the Bay Area have been lost to diking, draining, and filling.[859] The South Bay supports some of the most important habitat remaining in the entire Bay Area for a number of wildlife species, in spite of the highly urbanized surrounding areas and the dramatic alteration of the Bay itself for shipping, salt production, and urban development.[860] Wetland and jurisdictional waters restoration projects within the Bay area extensive, with approximately 40,000 acres of wetlands are either in progress or planned.[861] Although these restoration projects are attempting to reduce the cumulative loss of these habitats within the Region, the large historical loss of these areas has resulted in a cumulatively significant loss of wetlands and jurisdictional waters within the Region.

- As detailed in Table III.N-4, the Project would permanently impact 0.74 acre of wetlands and 24.97 acres of Section 404 other waters. The Project may also permanently impact 0.0992 acre and temporarily impact 0.1532 acre of a proposed Navy wetland mitigation site (refer to Figure III.N-6), if the mitigation site is constructed prior to construction of the Yosemite Slough bridge and its approaches. Temporary Project impacts would occur to 0.01 acre of wetlands and 2.76 acres of Section 404 other waters. Consequently,

[859] Goals Project. 1999. Baylands Ecosystem Habitat Goals. A report of habitat recommendations prepared by the San Francisco Bay Area Wetlands Ecosystem Goals Project. First Reprint. US Environmental Protection Agency, San Francisco, California/San Francisco Bay Regional Water Quality Control Board, Oakland, California.
[860] Goals Project. 1999. Baylands Ecosystem Habitat Goals. A report of habitat recommendations prepared by the San Francisco Bay Area Wetlands Ecosystem Goals Project. First Reprint. US Environmental Protection Agency, San Francisco, California/San Francisco Bay Regional Water Quality Control Board, Oakland, California.
[861] South Bay Salt Pond Restoration Project Final Environmental Impact Statement/Report. December 2007.

without mitigation of these impacts and compliance with regulations governing wetlands and jurisdictional waters, the Project would contribute to loss of wetlands and jurisdictional waters within the Region.

However, the Project also includes the removal of some shoreline structures (i.e., piers and/or bulkheads) and fill material that are currently present in jurisdictional areas. For example, portions of the Re-gunning pier and edges of bulkheads along much of the eastern part of HPS Phase II would be removed to create new open-water habitat. Although these areas are considered permanently impacted for the purposes of this impact assessment, since some fill would be placed along the new shoreline of these bulkheads for stabilization purposes, removal of structures and fill would restore approximately 8 acres of aquatic habitat. Considering that marsh restoration along the southern edge of HPS and portions of Candlestick Point is responsible for approximately 3 to 4 acres of impacts, approximately 11 to 12 acres of the total 28.48 acres of impacts to jurisdictional areas on the Project site would result from activities that would enhance ecological conditions along the shoreline.

- In response to public concerns, additional impacts to future wetland and aquatic habitat in consideration of the Yosemite Slough Restoration Project have been quantified. If the Restoration Project is implemented before the Yosemite Slough bridge is constructed, then the bridge would impact not only existing wetlands, aquatic habitats, and mud flats, but also sensitive habitats that have been restored by the Yosemite Slough Restoration Project. Based on the final Phase I Restoration Plan (on the north side of Yosemite Slough) provided by WRA, Inc. (the firm that designed the restoration plans) on 19 January 2010 and 50 percent plans for Phase II of the Restoration Plan (on the south side of Yosemite Slough) provided by WRA on 4 February 2010, additional impacts to sensitive habitats were calculated and are illustrated by Figure III.N-7 (Impacts to Wetlands and Other Waters after Yosemite Slough Wetland Restoration). Bridge construction access would result in temporary impacts to 0.21 acre of new vegetated tidal marsh that is proposed as part of the Yosemite Slough Restoration Project, but the CP-HPS Project would result in no permanent fill of new/restored wetland, aquatic, or mud flat habitat. Further, if the Restoration Project is implemented prior to bridge construction, shoreline improvements that would otherwise have been constructed to extend along the southern Yosemite Slough shoreline will not be necessary. Therefore, 0.03 acre of permanent impacts to wetlands and 0.19 acre of permanent impacts to Section 404 waters along the southern Yosemite Slough shoreline (off site) that were originally identified for the Project would not occur if Phase II of the Restoration Plan is implemented prior to bridge construction (though these existing jurisdictional areas would be temporarily impacted during bridge construction). Temporary impacts would be mitigated through implementation of mitigation measures MM BI-4a.1 and MM BI-4a.2, as required by the Project. Based on the plans for the restoration site provided by WRA as described above, less than 0.01 acre of wetlands that would be restored by the Restoration Project would be impacted by shading as a result of being located directly under the shadow of the bridge. If additional vegetated wetlands are proposed within the bridge footprint as design for Phase II of the Restoration Plan proceeds, such that additional shading impacts to vegetated wetlands would occur, and if such wetlands are constructed prior to construction of the bridge, mitigation for such impacts will be provided by the CP HPS Project at a 1:1 ratio as described above.

FIGURE III.N-7 Candlestick Point - Hunters Point Shipyard Phase II EIR

IMPACTS TO WETLANDS AND OTHER WATERS AFTER YOSEMITE SLOUGH WETLAND RESTORATION

Any alterations of, or discharges into, waters of the United States, including Section 404 wetlands must be in conformance with the CWA via Section 404 permitting and Section 401 certification prior to any grading or construction that may impact jurisdictional area(s), as appropriate. Additionally, a SAA per Section 1600 of the *California Fish and Game Code* would be required for removal of any CDFG-jurisdictional areas, if present. Also, runoff produced during and after construction is subject to NPDES and local water quality and runoff standards. Compensation for impacts to wetlands and jurisdictional waters are developed as a part of the permitting process with the USACE, or for non-USACE-jurisdictional wetlands, during permitting through the SFRWQCB, BCDC, and/or CDFG. The exact mitigation ratio is variable, and would be based on the type and value of the wetlands or jurisdictional waters affected, and would be established during the permitting process; however, at a minimum, compensation would result in compliance with the state[862] and federal[863] "no net loss of wetlands" policies, resulting in a minimum 1:1 mitigation ratio. Therefore, minimizing impacts to jurisdictional wetlands and other waters; compensating for impacts to these habitats; securing a SAA from the CDFG (if applicable) and 404 and 401 permits under the CWA; and compliance with the federal and state "no net loss of wetlands" policy would protect the hydrology and ecology of the wetlands and jurisdictional waters within the Project site and the Bay and its adjacent wetlands. Impacts from the Project to these habitats would thus be fully compensated. Therefore, because no long-term net loss of wetland resources would be attributable to the Project, development of the Project would not make a cumulatively considerable contribution to the regionally significant cumulative impact.

Interfere Substantially with Movement of Native Fish or Wildlife Species or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of a Native Wildlife Nursery Site (Criterion N.d)

The geographic context for the analysis of cumulative impacts on movement of native fish or wildlife species is the San Francisco Bay, both the aquatic portion and adjacent lands, which represents an area of possible connectivity or relationship in terms of wildlife movement. This area includes the shoreline and extends out into the Bay to include any area of in-water construction. The past and present development is described in the Setting section of this chapter, representing the baseline conditions for the evaluation of cumulative impacts. Reasonably foreseeable development would be those cumulative projects that could be developed in the specified geographic area.

Development over the past 150 years has encroached upon and displaced biological resources throughout the City of San Francisco and the areas surrounding the Bay. The conversion of grassland, oak woodland, riparian woodland, riverine, wetland, and other native habitats to urban and suburban development has not only resulted in considerable habitat loss, but has resulted in habitat fragmentation such that native non-avian wildlife species occurring in intact patches of native terrestrial habitat cannot readily access other intact terrestrial habitat patches. The lack of connectivity between native habitat patches has rendered many terrestrial species once common to those habitat patches susceptible to local extinction. In addition the conversion of the Bay's wetlands, eelgrass, and other aquatic habitats to other habitats and/or uses has resulted in these potential nursery sites being no longer available to the species that would have historically utilized them. Consequently, the conversion of open areas, both terrestrial and aquatic, on a Regional level

[862] http://ceres.ca.gov/wetlands/policies/governor.html.
[863] http://www.fws.gov/policy/660fw1.html.

as a result of cumulative development would result in a regionally significant cumulative impact on wildlife movement corridors and nursery sites.

Wildlife Movement

The Study Area does not include any regional wildlife corridor or migratory pathways. The site is surrounded by open water and urban development and contains no major drainages, canyon bottoms, ridgetops, rivers, creeks or areas that provide substantial movement corridors or migratory pathways. There would be no impact to regional terrestrial (non-avian) wildlife movement. The Project would be located along the Pacific Flyway for migratory birds. Migrating birds, such as songbirds, can be affected by human-built structures because of their propensity to migrate at night, their low flight altitudes, and their tendency to be disoriented by artificial light, making them vulnerable to collision with obstructions. This is a potentially significant cumulative impact. Mitigation measures MM BI-20a.1 and MM BI-20a.2 would reduce the Project's effects of operational activities related to tall structures and increased lighting to birds to less-than-significant levels by incorporating design features that would help minimize bird strikes, including using operation methods to reduce the effects of artificial lighting; making the structure, especially the glass surfaces, more visible from the outside with the use of external window coverings; and the creation of non-reflective or interference zones on or inside the glass. By implementing these measures, the design of towers that would be constructed in the Project area would be more "bird-friendly", thus resulting in less risk of avian collisions, than the numerous tall buildings that have been constructed in the region that were not designed and/or are not operated with minimizing avian collision risk in mind. Consequently, implementation of the Project would not interfere substantially with the movement of any native resident or migratory wildlife species or with established native resident or migratory wildlife corridors and the Project would not make a considerable contribution to this cumulative impact.

Nursery Sites

Construction of the Project and the cumulative projects on the shoreline or in-water in the vicinity of eelgrass beds could remove them or indirectly impact them such that productivity and survival of these habitats would be reduced. Eelgrass communities are considered important aquatic nursery sites as they serve as a haven for numerous aquatic species. Elimination of these important nursery areas would be a significant impact if it would impede the use of the eelgrass habitat. Mitigation measures MM BI-5b.1 through MM BI-5b.4 would reduce potential Project effects on eelgrass by requiring surveys for and avoidance of this habitat. For areas than cannot be avoided, this habitat would be replaced at a minimum ratio of 3:1 (i.e., 3 new acres of eelgrass to 1 removed acre) thus, replacing impacted habitat. Consequently, implementation of the Project would not impede the use of native wildlife nursery sites and the Project would not make a considerable contribution to this cumulative impact.

Overall, the Project's contribution to the cumulative impact on wildlife movement and wildlife nursery sites would be reduced to less than considerable by implementation of the above- mentioned mitigation measures. The Project's cumulative impact would, therefore, be less than significant.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
			PLANTS	
Adobe sanicle	*Sanicula maritima*	none/SR/1B.1	Chaparral, coastal prairie, meadows and seeps, and valley and foothill grasslands in association with clay or serpentine soils. 98–787 feet (30–240 meters); blooms February–May	**Not Likely.** Suitable habitat for this species occurs in the Study Area. However, there are no recorded occurrences of this species within 5 miles of the Study Area, and none were observed during rare plant surveys of suitable habitat in 2007 and 2008 by PBS&J.
Alkali milk-vetch	*Astragalus tener* var. *tener*	none/none/1B.2	Playas, valley and foothill grassland with adobe clay, and vernal pools with alkaline soils. 0–2051 feet (0–625 meters); blooms May–September.	**Not Likely.** Suitable habitat for this species does not occur in the Study Area.
Arcuate bush-mallow	*Malacothamnus arcuatus*	none/none/1B.2	Chaparral and cismontane woodland. 82–295 feet (25–90 meters); blooms April–September.	**Not Likely.** Suitable habitat for this species does not occur in the Study Area.
Beach layia	*Layia carnosa*	FE/SE/1B.1	Coastal dunes and coastal scrub with sandy soils. 0–197 feet (0–60 meters); blooms March–July.	**Not Likely.** Coastal scrub does not occur in the Study Area. This species was not observed during surveys conducted by PBS&J in 2007 and 2008.
Bent-flowered fiddleneck	*Amsinckia lunaris*	none/none/1B.2	Coastal bluff scrub, cismontane woodland, and valley and foothill grassland habitats. 10–1,640 feet (3– 500 meters); blooms March–June	**Not Likely.** Although there is one recorded occurrence of this species within 5 miles of the Study Area, no species of *Amsinckia* were observed during floristic surveys conducted in 2005 by CNPS[864] and in 2007 and 2008 by PBS&J.
Big-scale balsamroot	*Balsamorhiza macrolepis* var. *macrolepis*	none/none/1B.2	Occurs in chaparral, cismontane woodland, and valley and foothill grassland, sometimes in serpentine soil substrates at elevations ranging from 295–4,593 feet (90–1,400 meters); blooms March–June.	**Not Likely.** Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no species of *Balsamorhiza* were observed during floristic surveys conducted in 2005 by CNPS[865] and in 2007 and 2008 by PBS&J.
Blue coast gilia	*Gilia capitata* ssp. *chamissonis*	none/none/1B.1	Coastal dunes and coastal scrub. 7–656 feet (2–200 meters); blooms April–July.	**Not Likely.** Coastal scrub does not occur in the Study Area. There are no recorded occurrences of this species within 5 miles of the Study Area.
Bristly sedge	*Carex comosa*	none/none/2.1	Coastal prairie, marshes and swamps (along lake margins), and valley and foothill grassland. 0–2,051 feet (0–625 meters); blooms May–September.	**Not Likely.** Marsh habitat in the Study Area has been highly degraded. This species was not observed during surveys conducted by Caltrans in 2007.[866]

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
California seablite	*Suaeda californica*	FE/none/1B.1	Marshes and swamps with coastal salt marsh. 0–49 feet (0–15 meters); blooms July–October.	**Not Likely.** Marsh habitat in the Study Area has been highly degraded. This species was not observed during surveys conducted by Caltrans in 2007.[867]
Coastal triquetrella	*Triquetrella californica*	none/none/1B.2	A moss that occurs in coastal bluff scrub and coastal scrub. 33–328 feet (10–100 meters).	**Not Likely.** Coastal scrub does not occur in the Study Area.
Compact cobwebby thistle	*Cirsium occidentale* var. *compactum*	none/none/1B.2	Chaparral, coastal dunes, coastal prairie, and costal scrub. 16–492 feet (5–150 meters); blooms April–June.	**Not Likely.** Coastal scrub does not occur in the Study Area. No native species of *Cirsium* were observed during floristic surveys conducted in 2005 by CNPS[868] and in 2007 and 2008 by PBS&J.
Crystal Springs lessingia	*Lessingia arachnoidea*	none/none/1B.2	Cismontane woodland, coastal scrub, and valley and foothill grassland habitats, in association with serpentinite soils along roadsides. 197–656 feet (60–200 meters); blooms July–October	**Not Likely.** Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no species of *Lessingia* were observed during floristic surveys conducted by CNPS[869] and PBS&J in 2007 and 2008.
Diablo helianthella	*Helianthella castanea*	none/none/1B.2	Broadleafed upland forest, chaparral, cismontane woodland, coastal scrub, riparian woodland, and valley and foothill grassland. 197–4,265 feet (60–1,300 meters); blooms March–June.	**Not Likely.** Chaparral or oak woodland absent in Study Area.
Fountain thistle	*Cirsium fontinale* var. *fontinale*	FE/SE/1B.1	Openings in chaparral habitats; valley and foothill grassland habitats in association with serpentinite seeps. 295–574 feet (90–175 meters); blooms June–October	**Not Likely.** Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no native species of *Cirsium* were observed during floristic surveys conducted by CNPS[870] and PBS&J in 2007 and 2008.
Fragrant fritillary	*Fritillaria liliacea*	none/none/1B.2	Cismontane woodland, coastal prairie, coastal scrub, and valley and foothill grassland habitats often in association with serpentinite soils. 10–1,345 feet (3–410 meters); blooms February–April	**Not Likely.** Although there is one recorded occurrence of this species within 5 miles of the Study Area, no species of *Fritillaria* were observed during floristic surveys conducted by CNPS[871] and PBS&J in 2007 and 2008.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
Franciscan manzanita	*Arctostaphylos hookeri* ssp. *franciscana*	none/none/1A	Coastal scrub with serpentinite soil substrates. 197–984 feet (60–300 meters); blooms February–April.	**Not Likely.** Serpentinite soil substrates do not occur within Study Area. No recorded occurrences of this species within 5 miles of the Study Area. No species of *Arctostaphylos* were observed during surveys conducted by Caltrans in 2007[872] and PBS&J in 2007 and 2008.
Franciscan onion	*Allium peninsulare* var. *franciscanum*	SLC/none/1B.2	Clay and serpentine soils on dry hillsides in woodlands and valley and foothill grasslands 170–984 feet (52–300 meters); blooms May–June.	**Not Likely.** Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no species of *Allium* were observed during floristic surveys conducted by CNPS[873] and PBS&J in 2007 and 2008.
Franciscan thistle	*Cirsium andrewsii*	none/none/1B.2	Broadleafed upland forest, coastal bluff scrub, coastal prairie, and coastal scrub habitats, often in association with serpentinite soils. 0–492 feet (0–150 meters); blooms March–July	**Not Likely.** Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no native species of *Cirsium* were observed during floristic surveys conducted by CNPS[874] and PBS&J in 2007 and 2008.
Hillsborough chocolate lily	*Fritillaria biflora* var. *ineziana*	none/none/1B.1	Cismontane woodland and valley and foothill grassland habitats in association with serpentinite soils. 492 feet (150 meters); blooms March–April	**Not Likely.** Known only from the Hillsborough area. Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no native species of *Fritillaria* were observed during floristic surveys conducted by CNPS[875] and PBS&J in 2007 and 2008.
Kellogg's horkelia	*Horkelia cuneata* ssp. *sericea*	none/none/1B.1	Closed-cone coniferous forest, chaparral, coastal dunes, and coastal scrub with sandy or gravelly openings. 33–656 feet (10–200 meters); blooms April–September.	**Not Likely.** Coastal scrub does not occur in the Study Area.
Marin western flax	*Hesperolinon congestum*	FT/ST/1B.1	Chaparral and valley and foothill grassland habitats in association with serpentinite soils. 16–1214 feet (5–370 meters); blooms April–July	**Not Likely.** Although there are recorded occurrences of this species within 5 miles of the Study Area, no species of *Hesperolinon* were observed during floristic surveys conducted by CNPS and PBS&J in 2007 and 2008.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
Montara manzanita	*Arctostaphylos montaraensis*	none/none/1B.2	Chaparral and coastal scrub. 492–1,640 feet (150–500 meters); blooms January–March.	**Not Likely.** Coastal scrub does not occur in the Study Area. No species of *Arctostphylos* were observed during surveys conducted by Caltrans in 2007[876] and PBS&J in 2007 and 2008.
Most beautiful jewel-flower	*Streptanthus albidus* ssp. *permoenus*	none/none/1B.2	Chaparral, cismontane woodland, valley and foothill grasslands, often on serpentine soils. 361–3,281 feet (110–1,000 meters); blooms April–June.	**Not Likely.** Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no species of *Streptanthus* were observed during floristic surveys conducted by CNPS and PBS&J in 2007 and 2008.
Pacific manzanita	*Arctostaphylos pacifica*	none/SE/1B.2	Chaparral and coastal scrub. 1,083 feet (330 meters); blooms February–April.	**Not Likely.** Coastal scrub does not occur in the Study Area. Species of *Arctostaphylos* not identified during surveys.
Point Reyes bird's-beak	*Cordylanthus maritimus* ssp. *palustris*	none/none/1B.2	Coastal salt marsh. 0–33 feet (0–10 meters); blooms June–October.	**Not Likely.** Marsh habitat in the Study Area is of marginal quality and has been highly degraded. This species was not observed during surveys conducted by Caltrans in 2007.[877] Observed in adjacent off-site locations to the Yosemite Slough area according to the Yosemite Slough IS/MND.[878] Was not observed in the Yosemite Slough area during 2005 surveys conducted by LSA.
Presidio clarkia	*Clarkia franciscana*	FE/SE/1B.1	Occurs in coastal scrub and valley and foothill grassland, often on serpentine soils. 82–1,099 feet (25–335 meters); blooms May–July	**Not Likely.** Known from fewer than five occurrences. The closest two known populations are in the San Francisco Presidio approximately 6 miles northwest. Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no species of *Clarkia* were observed during floristic surveys conducted by CNPS[879] and PBS&J in 2007 and 2008.
Presidio manzanita	*Arctostaphylos hookeri ssp. ravenii*	FE/SE/1B.1	Chaparral, coastal prairie, and coastal scrub with serpentinite outcrops. 148–705 feet (45–215 meters); blooms February–March.	**Not Likely.** Serpentinite soil substrates do not occur within Study Area; however, there are no recorded occurrences of this species within 5 miles of the Study Area. Species of *Arctostaphylos* not identified during surveys.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
Robust spineflower	*Chorizanthe robusta* var. *robusta*	FE/none/1B.1	Chaparral, cismontane woodlands (in openings), coastal dunes, coastal scrub with sandy or gravelly soil. 10–984 feet (3–300) meters; blooms April–September.	**Not Likely.** Coastal dunes are absent from the Study Area. Remnant dunes in the Study Area are disturbed habitat. This species was not observed during surveys conducted by PBS&J in 2007 and 2008.
Rose leptosiphon	*Leptosiphon rosaceus*	none/none/1B.1	Coastal bluff scrub. 0–328 feet (0–100 meters); blooms April–July.	**Not Likely.** Suitable habitat for this species does not occur in the Study Area.
San Bruno Mountain manzanita	*Arctostaphylos imbricata*	none/SE/1B.1	Chaparral and coastal scrub with rocky substrate. 902–1,214 feet (275–370 meters); blooms February–May.	**Not Likely.** Coastal scrub does not occur in the Study Area. Species of *Arctostaphylos* not identified during surveys.
San Francisco Bay spineflower	*Chorizanthe cuspidate* var. *cuspidata*	none/none/1B.2	Coastal bluff scrub, coastal dunes, coastal prairie, and coastal scrub with sandy soils. 10–705 feet (3–215 meters); blooms April–July (uncommon in August).	**Not Likely.** Coastal scrub does not occur in the Study Area.
San Francisco campion	*Silene vercunda* ssp. *verecunda*	none/none/1B.2	Coastal bluff scrub, chaparral, coastal prairie, coastal scrub, and valley and foothill grassland with sandy soil. 98–2,116 feet (30–645 meters); blooms March–June (uncommon in August).	**Not Likely.** Coastal scrub does not occur in the Study Area.
San Francisco Collinsia	*Collinsia multicolor*	none/none/1B.2	Closed-cone coniferous forest and coastal scrub (sometimes with serpentinite soil). 98–820 feet (30–250 meters); Blooms March–May.	**Not Likely.** Coastal scrub does not occur in the Study Area.
San Francisco gumplant	*Grindelia hirsutula* var. *maritima*	none/none/1B.2	Coastal bluff scrub, coastal scrub, and valley and foothill grassland habitats in association with sandy or serpentinite soils. 49–1,312 feet (15–400 meters); blooms June–September	**Not Likely.** Although there are a number of recorded occurrences of this species within 5 miles of the Study Area, this species was not observed during floristic surveys conducted by CNPS[880] and PBS&J in 2007 and 2008.
San Francisco Lessingia	*Lessingia germanorum*	FE/SE/1B.1	Coastal scrub (remnant dunes). 82–295 feet (25–90 meters); blooms July–November (uncommon in June).	**Not Likely.** Coastal scrub does not occur in the Study Area. This species was not observed in sandy soil areas during surveys; no species of *Lessingia* were observed during floristic surveys conducted by CNPS[881] and PBS&J in 2007 and 2008.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
San Francisco owl's-clover	*Triphysaria floribunda*	none/none/1B.2	Coastal prairie, coastal scrub, and valley and foothill grassland habitats in association with serpentinite soils. 33–525 feet (10–60 meters); blooms April–June	**Not Likely.** Although there is one recorded occurrence of this species within 5 miles of the Study Area, no species of *Triphysaria* has been observed during floristic surveys conducted by CNPS[882] and PBS&J in 2007 and 2008.
San Francisco popcornflower	*Plagiobothrys diffusus*	None/SE/ 1B.1	Occurs in coastal prairie and valley and foothill grassland. 197–1,181 feet (60–360 meters); blooms March–June.	**Not Likely.** Known from fewer than ten occurrences. Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no species of *Plagiobothrys* were observed during floristic surveys conducted by CNPS[883] and PBS&J in 2007 and 2008.
SanMateo thorn-mint	*Acanthomintha duttonii*	FE/SE/1B.1	Chaparral and valley and foothill grassland habitats, often on serpentinite soil substrates. 164–984 feet (50–300 meters); blooms April–June	**Not Likely.** Serpentinite soil substrates do not occur within Study Area, however there are no recorded occurrences of this species within 5 miles of the Study Area; species of *Acanthomintha* were not observed during floristic surveys conducted by CNPS[884] and PBS&J in 2007 and 2008.
Santa Cruz microseris	*Stebbinsoseris decipiens*	none/none/1B.2	Openings in broadleafed upland forest, closed-cone coniferous forest, chaparral, coastal prairie, coastal scrub, valley and foothill grasslands, sometimes on serpentine soils. 33–1,640 feet (10–500 meters); blooms April–May.	**Not Likely.** Although potentially suitable habitat and soil substrates are present, there are no recorded occurrences of this species within 5 miles of the Study Area; no species of *Stebbinsoseris* were observed during floristic surveys conducted by CNPS[885] and PBS&J in 2007 and 2008.
Short-leaved evax	*Hesperevax sparsiflora* var. *brevifolia*	none/none/2.2	Coastal bluff with sandy soil and coastal dunes. 0–705 feet (0–215 meters); blooms March–June.	**Not Likely.** Suitable habitat for this species does not occur in the Study Area.
White-rayed pentachaeta	*Pentachaeta bellidiflora*	FE/SE/List 1B.1	Occurs in cismontane woodland and valley and foothill grassland, often in serpentinite. 115–2034 feet (35–620 meters); blooms March–May	**Not Likely.** Although there is one recorded occurrence of this species within 5 miles of the Study Area, no species of *Pentachaeta* were observed during floristic surveys conducted by CNPS[886] and PBS&J in 2007 and 2008.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
			SENSITIVE NATURAL COMMUNITIES	
Coastal brackish marsh (salt marsh)		CDFG Sensitive Habitat		**Known.** The Study Area supports representative assemblages of plant species associated with this community type. Degraded occurrences of this sensitive natural community are present along the southern portion of HPS Phase II site, along Yosemite Slough, and patches along the Candlestick Point shoreline.[887]
			INVERTEBRATES	
Bay checkerspot butterfly	*Euphydryas editha bayensis*	FT/none/none Critical habitat	All habitats for the bay checkerspot are on shallow, serpentine-derived, or similar soils. These soils support the plants on which the caterpillars (larvae) feed the primary larval host plant is dwarf plantain (*Plantago erecta*). In many years, the plantain dries up and the larvae transfer to a second host plant, Indian paintbrush, or purple owl's clover (*Castilleja exserta* spp. *exerta*), which remains edible later in the season.	**Not Likely.** It is not likely that there is a sufficient population of plantain to support Bay checkerspot in the Study Area.[888] Sites that support this species provide greater topographic heterogeneity than the serpentine grassland in the Study Area. Although there are a number of recorded occurrences for this species within 5 miles of the Study Area, this species was extirpated from the closest location of historical occurrence (San Bruno Mountain) in the 1980's.
Callippe silverspot butterfly	*Speyeria callippe callippe*	FE/none/none	Occurs in grassland habitats around the northern Bay Area containing Johnny jump-up (*Viola pedunculata*), which is the larval host plant for this species.	**Not Likely.** Although there are a number of recorded occurrences within 5 miles of the Study Area, *V. pedunculata* has not been observed within the Study Area. In addition, although there are nearby occurrences, there is an insufficient population of this species' host plant within the Study Area to sustain a population of this species.[889]

[887] H.T. Harvey & Associates, Hunters Point Shipyard and Candlestick Point State Recreation Area Final Delineation of Wetlands and Other Waters, San Francisco, California, February 2009 and revised July 13, 2009 and October 2, 2009.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
Mission blue butterfly	*Plebejus* [*Icaricia*] *icarioides missionensis*	FE/none/none	The adults feed on hairy false goldenaster (*Heterotheca villosa*), blue dicks (*Dichelostemma capitatum*), and seaside buckwheat (*Eriogonum latifolium*). They do not wander far from the three species of lupine that are the larval food plant: silver lupine (*Lupinus albifrons*), summer lupine (*L. formosus*), and many-colored lupine (*L. versicolor*). Females lay eggs throughout the mating flight. The eggs are laid singly on leaves, stems, flowers, and seedpods of lupine species.	**Not Likely.** Although there are a number of recorded occurrences for this species within 5 miles of the Study Area, including one from the Bayview Hill area, the Study Area does not support a substantial stand of lupine (*Lupinus* spp.) to support this species.[890] Isolated lupine plants intermixed within ruderal vegetation was observed along the Candlestick Point area, near Yosemite Slough. One or two lupine plants were observed in this area during the May 5, 2008 survey, but this would not constitute habitat for this species.
Monarch butterfly (wintering)[891]	*Danaus plexippus*	none/none/ESHA	Occur in many open habitats including fields, meadows, weedy areas, marshes, and roadsides. Adults migrate from August to October, flying south to hibernate along the California coast and in central Mexico. During migration and wintering, butterflies roost in trees and form huge aggregations. Caterpillars feed exclusively on milkweed (*Asclepias* spp.); early in the season, adults sip nectar from dogbane (*Apocynum* spp.), lilac (*Ceanothus* spp.), red clover (*Trifolium pratense*), *Lantana* spp., and thistles (*Cirsium* spp.). In the fall adults visit composites including goldenrods (*Solidago californica*), blazing stars (*Liatris spicata*), ironweed (*Vernonia* spp.), and tickseed sunflower (*Bidens* spp.).	**Known, but Not Likely roosting.** Although individuals have been observed on the site, there is no record of monarch butterfly autumnal (i.e., temporary bivouac site) or over-wintering use of the Study Area in the CNDDB and other records, including anecdotal observations. The nearest observations of such roosts are at Fort Mason, the Presidio of San Francisco, and Stern Grove. The modification of Hunters Point and Candlestick Park would not affect those sites.[892]
Myrtle's silverspot butterfly	*Speyeria zerene myrtleae*	FE/none/none	Occurs in grassland habitats around the northern Bay Area. The larval host plant is hookspur violet (*Viola adunca*). Adults feed on nectar from flowers including hairy gumweed, coastal sand verbena (*Abronia latifolia*), mints (or monardella) (*Monardella* spp.), bull thistle (*Cirsium vulgare*), and seaside fleabane (*Erigeron glaucus*).	**Not Likely.** There are no recorded occurrences of this species within 5 miles of the Study Area. The Study Area does not support the suitable host plants for this species.

[890] United States Fish and Wildlife Service (USFWS), Endangered and Threatened Wildlife and Plants*: Proposed Determination of Critical Habitat for Six Butterflies and Two Plants*, 42 Federal Register 7972, February 8, 1977.
[891] Wintering habitat is considered an Environmentally Sensitive Habitat Area by the California Coastal Commission.
[892] Monroe, M., Ranger, Muir Woods National Monument, telephone conversation with Todd Wong, July 16, 2008.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
San Bruno elfin butterfly	*Callophyrs* [*Incisalia*] *mossii bayensis*	FE/none/none	Endemic to the coastal mountains near San Francisco Bay. Eggs are laid in small clusters or strings on the upper or lower surface of broadleaf stonecrop (*Sedum spathulifolium*). The adult food plants have not been fully determined but Montara Mountain colonies are suspected to use Montara manzanita (*Arctostaphylos montaraensis*) and California huckleberry (*Vaccinium ovatum*).	**Not Likely.** There are a number of recorded occurrences for this species within 5 miles of the Study Area. However, the San Bruno elfin is found in the fog-belt of steep north facing slopes that receive little direct sunlight. It lives near prolific growths of the larval food plant, stonecrop, which is a low growing succulent. The Study Area does not support suitable larval and adult host plants.[893]
			MOLLUSKS	
Black abalone	*Haliotes cracherodii*	FC/none/none	Endemic to Santa Barbara Channel Islands.	**Absent.** The Study Area is outside the range of this species.
White abalone	*Haliotes sorenseni*	FE/none/none	Rocky marine subtidal (to 200 feet deep) and extreme lower intertidal (below 15 feet deep) habitats. Current population extremely depleted.	**Absent.** The Study Area is too shallow and modified to provide suitable habitat.
Olympia oyster	*Ostreola conchaphila*	none/none/CEQA	Native Olympia oysters were historically abundant in San Francisco Bay, and small populations of native oysters have been documented within the Bay. Suitable substrate includes solid surfaces to which the larvae can easily attach.	**High.** Because the larval forms of oysters are free-floating in the Bay and a large population exists south of the Study Area at Oyster Point Marina, native oysters are likely present on suitable substrate throughout the Study Area.
			FISH	
Pacific herring	*Clupea pallasi*	none/none/CEQA	Pacific herring generally enter the Bay from November through April of each year and spawn in intertidal and sub-tidal habitats.	**Known**. According to NMFS, known herring spawning areas within the Study Area include several piers and areas of shoreline both north and south of the proposed marina.
Chinook salmon –Spring-run ESU	*Oncorhynchus tshawytscha*	FT/ST/none	Central Valley streams with stable water supply, clean gravel, and good quality riparian habitat. Spawning occurs only in tributaries to the Sacramento River.	**Low.** The Study Area is outside the migratory corridor for this species. Adults migrate from the Golden Gate into the Sacramento River.
Chinook salmon –Winter-run ESU	*Oncorhynchus tshawytscha*	FE/ST/none Critical habitat	Central Valley streams with stable water supply, clean gravel, and good quality riparian habitat. Spawning occurs upstream of the Red Bluff Diversion Dam.	**Low.** The Study Area is generally outside the migratory corridor for this species. Adults migrate from the Golden Gate into the Sacramento River. Study Area is outside of designated critical habitat.

[893] Kobernus, P., Senior Biologist, TRA Environmental Sciences, Inc., email to PBS&J, August 30, 2007.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
Chinook salmon –Fall/Late Fall-run ESUs	*Oncorhynchus tshawytscha*	SC/SSC/none	The most abundant Chinook in the Central Valley. Fall/Late fall-run fish spawn in streams with stable water supply, clean gravel, and good quality riparian habitat.	**Low.** The Study Area is generally outside the migratory corridor for this ESU. A population exists in the South Bay that would migrate past the Study Area on the way to and from the ocean. The origin and status of this population is unclear (refer to text).
Coho salmon—Central California ESU	*Oncorhynchus kisutch*	FE/SE/none	Spawning in accessible coastal streams, generally in areas with complex instream habitat, heavy forest cover, and high quality water. Juveniles rear in these areas for two years before migrating to the ocean.	**Absent.** This species does not currently exist in the San Francisco Bay.[894]
Delta smelt	*Hypomesus transpacificus*	FT/SE/none	Endemic to the Sacramento-San Joaquin Delta. Adults spawn in freshwater in the upper Delta. The rest of the year, they reside primarily in the interface between salt and freshwater of the Sacramento-San Joaquin Delta at salinities less than 2 parts per million.	**Absent.** The Study Area is outside the known range of this species.
Longfin smelt	*Spirinchus thaleichthys*	none/ST/none	Native to San Francisco Bay. Adults spawn in upper estuary in early winter. Larvae are dispersed by downstream flow and distribution is determined by outflow. Adults found outside the Bay in some years.	**Moderate.** Based on a 2009 status review, distribution of larval fish is determined by outflow from the Sacramento-San Joaquin River Estuary where adults spawn.[895] As they develop swimming ability, they could disperse into the Study Area. They are captured as by-catch in the Bay for bay shrimp (*Crangon franciscorum*).
Green sturgeon	*Acipenser medirostris*	FT/SSC/none Proposed Critical Habitat	Migrates through the San Francisco Bay to spawning grounds in the upper Sacramento River. Juveniles move into the estuary and likely rear in San Francisco Bay.	**High.** The species likely forages in the Bay including the area near the Study Area. The Study Area is within proposed critical habitat for this species.
Steelhead—Central California Coast DPS	*Oncorhynchus mykiss*	FT/none/none Critical habitat	Spawns in cool, clear, well-oxygenated streams. Juveniles remain in fresh water for one or more years before migrating to the ocean.	**High.** Juveniles and adult steelhead could be found in the open waters adjacent to the Study Area as they migrate to and from streams in the San Francisco Bay. Populations are known from relatively nearby creeks on the peninsula (i.e., San Francisquito Creek). The Study Area is within designated critical habitat for this DPS.
Steelhead—Central Valley DPS	*Oncorhynchus mykiss*	FT/none/none Critical habitat	Spawns in cool, clear, well-oxygenated streams. Juveniles remain in freshwater for one or more years before migrating to the ocean.	**Low.** Even though their primary migratory pathway is into the Sacramento River, juveniles and adult steelhead could potentially be found in the Bay near the Project. The Study Area is outside of designated critical habitat for this DPS.

[894] Jones and Stokes, Biological Assessment for the Bayview Transportation Improvements Project, June 2009.
[895] California Department of Fish and Game (CDFG), *A Status Review of the Longfin Smelt (Spirinchus thaleichthys) in California, January 2009*.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
Tidewater goby	*Eucyclogobius newberryi*	FE/SSC/none	Brackish water habitats along coast, fairly still but not stagnant water and high oxygen levels.	**Absent.** The shoreline of the Study Area is influenced by tidal activity. Brackish water habitat absent. Due to degradation lagoon/estuary habitat does not exist.[896]
			AMPHIBIANS	
California red-legged frog	*Rana aurora draytonii*	FT/SSC/none	Permanent and semi-permanent freshwater habitats, such as creeks and cold-water ponds, with emergent and submergent vegetation.	**Not Likely.** Perennial freshwater habitat is absent from the Study Area. There are no CNDDB records for this species in the vicinity of the Study Area.
			REPTILES	
Green turtle	*Chelonia mydas*	FT/none/none	Shallow water with sufficient submergent vegetation. Breeds on islands often but also on mainland sandy beaches.	**Absent.** Suitable habitat for this species does not occur in the Study Area.
Leatherback turtle	*Dermochelys coriacea*	FE/none/none	Marine, open ocean often near continental shelf. Nests on sloped sandy beaches often near deep water.	**Absent.** Suitable habitat for this species does not occur in the Study Area.
Loggerhead turtle	*Caretta caretta*	FT/none/none	Open ocean up to 500 miles off shore. Nests on sandy beaches seaward of well developed dunes.	**Absent.** Suitable habitat for this species does not occur in the Study Area.
Olive (=Pacific) ridley sea turtle	*Lepidochelys olivacea*	FT/none/none	Near shore less and 15 km. bottom dwelling sea turtle, nests on sandy beaches.	**Absent.** Suitable habitat for this species does not occur in the Study Area.
San Francisco garter snake	*Thamnophis sirtalis tetrataenia*	FE/ST/FP	Inhabits ponds, streams, rivers, and reservoirs, typically with riparian or emergent vegetation. Requires upland areas for aestivation and nesting, usually within 100 yards of permanent water source.	**Not Likely.** Suitable habitat for this species does not occur in the Study Area. There are no CNDDB records for this species in the vicinity of the Study Area.
Western pond turtle	*Actinemys marmorata*	none/SSC/none	Typically inhabit ponds, slow-moving streams and rivers, irrigation ditches, and reservoirs with abundant emergent and/or riparian vegetation.	**Not Likely.** Suitable habitat for this species does not occur in the Study Area. There are no CNDDB records for this species in the vicinity of the Study Area.
			BIRDS	
Alameda song sparrow	*Melospiza melodia pusillula*	none/SSC/none	Tidal salt marsh habitats along the edge of the Bay and streams where tidal flow effects the vegetation.	**Low.** Salt marsh along Yosemite Slough and the HPS shoreline provides marginal habitat for this species due to its limited extent. Song sparrows were observed between January 2003 and April 2004 along Yosemite Slough, however it is unknown whether these were Alameda song sparrows.

[896] Jones and Stokes, *Biological Assessment for the Bayview Transportation Improvements Project*, June 2009.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
American peregrine falcon (nesting)	*Falco pergrinus anatum*	Delisted/SE (proposed delisted)/FP	Frequents bodies of water in open areas with cliffs and canyons nearby for cover and nesting. Known to nest on artificial substrates (bridges, buildings, etc)	**Known.** A pair of American Peregrine falcons was observed nesting in the Re-gunning crane on Parcel D of the HPS Phase II site. The pair has raised several young at this location.[897]
Bank swallow (nesting)	*Riparia riparia*	none/ST/none	Nests in steep sandy banks where it excavates burrows.	**Not Likely.** Although individuals have been observed in the vicinity, the Study Area does not provide suitable nesting habitat.
Barrow's goldeneye	*Bucephala islandica*	none/SSC/none	Breeds in high central & northern Sierra Nevada Mountains, near wooded mountain lakes or large streams. Nest in tree cavities, such as a deserted nest-hole of a pileated woodpecker or flicker; also use nest boxes.	**Known.** Although observed near the site during migration and winter, the Study Area does not provide suitable nesting habitat and is well outside the species' breeding range.
Bryant's savannah sparrow	*Passerculus sandwichensis alaudinus*	none/SSC/none	Frequents low tidally influenced habitats, adjacent to ruderal areas, moist grasslands within and just above the fog belt, and grasslands.	**Low.** Salt marsh along Yosemite Slough and the HPS shoreline provides marginal habitat for this species due to its limited extent. Savannah sparrows were observed between January 2003 and April 2004 along Yosemite Slough, however it is unknown whether these were Bryant's savannah sparrows.
Burrowing owl	*Athene cunicularia*	none/SSC/none	Found in open, dry grasslands, deserts, and ruderal areas. Requires suitable small mammal burrows.	**Known.** This species has been observed in the past on Candlestick Point and at HPS, and suitable foraging habitat is present on the site. Although suitable conditions for nesting are present, the species is not known to have nested on the site. Currently, it is either absent, or it occurs sporadically as a non-breeding visitor.
California black rail	*Laterallus jamaicensis coturniculus*	none/ST/FP	Inhabits tidal salt marshes bordering larger bays, or other freshwater and brackish marshes, at low elevations.	**Not Likely.** Small mats of pickleweed adjacent to brackish wetlands are too limited in extent and too highly disturbed to provide suitable habitat. Tidal zone is very narrow.
California brown pelican (rookery and communal roosts)	*Pelecanus occidentalis californicus*	FPD/SPD[898]/FP	Typically in littoral ocean zones, just outside the surf line; nests on offshore islands.	**Known.** This species was observed roosting on piers within the Study Area. However, suitable nesting habitat for this species does not occur in the Study Area. The Study Area is outside this species' current breeding range.

[897] Nelson, G., Facility Coordinator, Navy, field visit with PBS&J, July 8, 2008.
[898] California Department of Fish and Game (CDFG) news release: *Fish and Game Commission votes to remove California brown pelican from State Endangered Species List*. February 17, 2009.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
California clapper rail	*Rallus longirostris obsoletus*	FE/SE/FP	Restricted to salt marshes and tidal sloughs; usually associated with heavy growth of pickle-weed; feeds on mollusks removed from the mud in sloughs.	**Not Likely.** Suitable habitat does not occur in the Study Area. Salt marsh is highly disturbed and limited in the Study Area. Yosemite Slough is a tidal slough, but suitable habitat for the rail is absent because the existing salt marsh in Yosemite Slough is very narrow and unsuitable. The lack of tidal channels within those marshes, feeding into Yosemite Slough further reduce habitat quality.
California least tern (nesting colony)	*Sternula antillarum browni*	FE/ST/FP	Nests on sandy, upper ocean beaches, and occasionally uses mud flats; forages on adjacent surf line, estuaries, or the open ocean.	**Not Likely.** Suitable nesting habitat does not occur in the Study Area. Individuals may forage in the open water adjacent to the Study Area.
Common loon	*Gavia immer*	none/SSC/none	Nesting locations at certain large lakes & reservoirs in interior of state, primarily in northeastern plateau region. Bodies of water regularly frequented are extensive, fairly deep, and produce quantities of large fish.	**Known.** Although observed near the site during migration and winter, the Study Area does not provide suitable nesting habitat and is well outside the species' breeding range.
Harlequin duck (nesting)	*Histrionicus histrionicus*	none/SSC/none	Usually nests along shores of shallow, swift rivers with plentiful aquatic invertebrates.[899]	**Known.** This species was observed perching on the piers in the HPS Phase II site. However, the Study Area does not provide suitable nesting habitat for this species. The Study Area is outside this species' current breeding range.
Loggerhead shrike	*Lanius ludovicianus*	none/SSC/none	Prefers open country for hunting, with perches for scanning, and fairly dense shrubs and brush for nesting. Typically nests in broken woodlands, savannah, pinyon-juniper, Joshua tree, and riparian woodlands, desert oases, scrub, and wash.	**Known.** Non-native grasslands provide suitable foraging habitat. Loggerhead shrike has been observed by Alan Hopkins at the CPSRA.[900] Although suitable conditions for nesting are present, the species is not known to have nested on the site. Currently, it is either absent, or it occurs sporadically as a non-breeding visitor.
Marbled murrelet	*Brachyramphus marmoratus*	FT/SE/none	Mature, coastal coniferous forests for nesting; nearby coastal water for foraging; nests in conifer stands greater than 150 years old and may be found up to 35 miles inland; winters on subtidal and pelagic waters often well offshore.	**Absent.** Suitable habitat not present in the Study Area.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
Northern harrier	*Circus cyaneus*	none/SSC/none	Coastal salt & fresh-water marsh. Nest & forage in grasslands, from salt grass in desert sink to mountain cienegas. Nests on ground in shrubby vegetation, usually at marsh edge; nest built of a large mound of sticks in wet areas.	**Known.** Salt marsh and ruderal habitats provide suitable foraging habitat for this species, which has been observed by Alan Hopkins at the CPSRA.[901] However, suitable breeding habitat is absent due to the limited extent of marsh, human disturbance, and vulnerability of this ground-nesting species to predation.
San Francisco yellowthroat	*Geothlypis trichas sinuosa*	none/SSC/none	Inhabits emergent wetland habitat, and is a resident and summer visitor in the San Francisco Bay area. Nests are usually placed on or within 8 cm (3 inches) of ground; and may be positioned over water in emergent aquatic vegetation, dense shrubs, or other dense growth.	**Moderate.** Salt marsh along Yosemite Slough and the HPS shoreline provides potential habitat for this species. The existing salt marsh provides marginal habitat due to its limited extent. Common yellowthroats were observed between January 2003 and April 2004 along Yosemite Slough, however it is unknown whether these were San Francisco yellowthroats.[902]
Short-eared owl	*Asio flammeus*	none/SSC/none	Found in swamplands, both fresh and salt; lowland meadows; irrigated alfalfa fields. Tule patches/tall grass needed for nesting/daytime seclusion. Nests on dry ground in depression concealed in vegetation.	**Known.** Salt marsh and ruderal habitats provide suitable foraging habitat for this species, which has been observed by Alan Hopkins at the CPSRA.[903] However, suitable breeding habitat is absent due to the limited extent of marsh, human disturbance, and vulnerability of this ground-nesting species to predation.
Short-tailed albatross	*Phoebastria albatrus*	FE/none/none	Pelagic; nests on offshore islands in north Pacific.	**Absent.** Suitable habitat does not occur in the Study Area.
Tricolored Blackbird	*Agelaius tricolor*	none/SSC/none	Highly colonial species, most numerous in central valley & vicinity. Largely endemic to California. Requires open water, protected nesting substrate, & foraging area with insect prey within a few km of the colony.	**Known.** Ruderal and developed areas on the site provide potential foraging habitat for this species, and the tricolored blackbird has been observed by Alan Hopkins at the CPSRA.[904] However, suitable nesting habitat is absent due to the lack of extensive freshwater marsh vegetation.
Vaux's swift	*Chaetura vauxi*	none/SSC/none	Redwood, Douglas fir, & other coniferous forests. Nests in large hollow trees & snags. Often nests in flocks. Forages over most terrains & habitats.	**Known.** Suitable nesting habitat does not occur in the Study Area. However, individuals may forage aerially over the Study Area.
Western snowy plover (nesting)	*Charadrius alexandrinus nivosus*	FT/SSC/none	Coastal beaches above the normal high tide line in flat, open areas with sandy or saline substrates; vegetation and driftwood are usually sparse or absent.	**Not Likely.** Extensive, open sandy substrate to provide nesting habitat within the Study Area is absent.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*
White-tailed kite	*Elanus leucurus*	none/none/FP	Preferred habitat is marshes and waste fields in the Central Valley and coastal plains of California.	**Known.** Non-native grasslands provide suitable foraging habitat. Large trees in the Study Area provide suitable nesting habitat for this species, although the species is not known to nest there.
			MAMMALS	
Blue whale	*Balaenoptera musculus*	FE/none/none	Coastal and pelagic environments frequently found on the continental shelf off the California coast.	**Absent.** Suitable habitat does not occur in the Study Area.
Finback whale	*Balaenoptera physalus*	FE/none/none	Pelagic; usually found 25 miles or more off shore.	**Absent.** Suitable habitat does not occur in the Study Area.
Guadalupe fur seal	*Arctocephalus townsendii*	FT/ST/FP	Rocky insular shorelines and sheltered coves.	**Absent.** Suitable habitat does not occur in the Study Area.
Right whale	*Eubalaena glacialis*	FE/none/none	Pelagic, occurs mainly over continental shelf in the Pacific Ocean.	**Absent.** Suitable habitat does not occur in the Study Area.
Salt marsh harvest mouse	*Reithrodontomys raviventris*	FE/SE/FP	Salt marshes with a dense plant cover or pickleweed or fat hen; adjacent to an upland site.	**Not Likely.** Small mats of pickleweed adjacent to brackish wetlands and salt marsh habitat in the Study Area are highly disturbed. This species has not been recorded on the Peninsula north of the Foster City/ San Mateo Bridge area in decades.
Sei whale	*Balaenoptera borealis*	FE/none/none	Pelagic; generally in deep water along continental shelf.	**Absent.** Suitable habitat does not occur in the Study Area.
Sperm whale	*Physeter catodon*	FE/none/none	Pelagic; prefers deep water but is sometimes found around islands or in shallow shelf waters.	**Absent.** Suitable habitat does not occur in the Study Area.
Steller sea-lion	*Eumetopias jubatus*	FT/none/none Critical habitat	Near shore, pelagic when in water. Otherwise on shore, talus or bare rocks. Critical habitat has been defined for stellar sea lion as a 20 nautical mile buffer around all major haulouts and rookeries, as well as associated terrestrial, air and aquatic zones, and three large offshore foraging areas.[905]	**Not Likely.** Suitable habitat does not occur in the Study Area. Designated critical habitat does not occur in the Study Area. The closest designated critical habitat for this species is the Farallon Islands, approximately 33 air miles east of the Study Area.
Western red bat	*Lasiurus blossevillii*	none/SSC/none	Roosts primarily in trees, less often in shrubs, adjacent to streams, fields, or urban areas. Preferred roost sites are protected from above, open below, and located above dark ground cover.	**Moderate.** Trees (such as eucalyptus) provide potential roost sites for solitary migrant individuals.

Table III.N-5 Special-Status Species Potentially Occurring within the Study Area

Common Name	*Scientific Name*	*Status[a] Fed/ CA/ other*	*Habitat and Seasonal Distribution in California*	*Likelihood of Occurrence Within the Study Area*

a. Status:

Federal

FE Federally listed as Endangered
FT Federally listed as Threatened
FC Federal candidate species
FPD Federally Proposed Delisted
SC National Marine Fisheries Service designated Species of Concern. Species of Concern status does not carry any procedural or substantive protections under the FESA.

State

SE State listed as Endangered
ST State listed as Threatened
SPD State Proposed for Delisting
SR State Rare
FP California Department of Fish and Game designated "Fully Protected"
SSC California Department of Fish and Game designated "Species of Special Concern"

Other

ESHA Environmentally Sensitive Habitat Area by the California Coastal Commission
SLC California Native Plant Society (CNPS) Ranking Species of Local Concern
1B California Native Plant Society (CNPS) Ranking. Defined as plants that are rare, threatened, or endangered in California and elsewhere.
2 California Native Plant Society (CNPS) Ranking. Defined as plants that are rare, threatened, or endangered in California, but more common elsewhere.
3 California Native Plant Society (CNPS) Ranking. Plants About Which More Information is Needed—A Review List.
CEQA Species not currently protected by statute or regulation, but considered rare, threatened or endangered under Section 15380 of the CEQA Guidelines.
Recent modifications to the CNPS Ranking System include the addition of a new Threat Code extension to listed species (i.e., List 1B.1, List 2.2 etc.). A Threat Code extension of .1 signifies that a species is seriously endangered in California; .2 is fairly endangered in California; and .3 is not very endangered in California.

b. Likelihood of occurrence evaluations

- A rating of "**Known**" indicates that the species/natural community type has been observed on the site.
- A rating of "**High**" indicates that the species has not been observed, but sufficient information is available to indicate suitable habitat and conditions are present in the Study Area and the species is expected to occur in the Study Area.
- A rating of "**Moderate**" indicates that it is not known if the species is present, but suitable habitat exists in the Study Area.
- A rating of "**Low**" indicates that species was not found during biological surveys conducted to date on the Project site and may not be expected given the species' known regional distribution or the quality of habitats located in the Study Area.
- A rating of "**Not Likely**" indicates that the taxon would not be expected to occur in the Study Area because the Study Area does not include the known range or does not support suitable habitat.
- A rating of "**Absent**" indicates that no recorded occurrences or suitable habitat(s) occur within the Study Area to support this species. These species are not discussed further in this document.

SECTION III.O PUBLIC SERVICES

III.O.1 Introduction

This section of the EIR discusses public services, including police protection, fire protection, schools, and libraries, and whether the Project would require new or expanded facilities to maintain acceptable service levels. If the population increase or development levels associated with the Project were to trigger a need for expansion or construction of new public facilities, this section analyzes whether the resulting physical changes could result in significant adverse environmental effects. In other words, an increase in staffing associated with public services or an increase in students would not, by itself, be considered a physical change in the environment; however, a physical change in the environment could result from the construction of new facilities or an expansion of existing facilities to accommodate the increased staff or students.

The EIR uses the most current information available since issuance of the Notice of Preparation for all of the public services analyzed in this section. The baseline conditions are identified under each public service category. This section identifies project-level and cumulative environmental impacts, as well as feasible mitigation measures that could reduce or avoid the identified impacts. Analysis of emergency access to the Project site is provided in Section III.D (Transportation and Circulation).

Police Protection

III.O.2 Setting

The San Francisco Police Department (SFPD) provides various public safety services in the City, including the Project site. These services include response to calls (reports of needs for police assistance), officer-initiated activity, traffic management, and general surveillance.

The Project site lies within the SFPD's Bayview District. Police services are provided from the Bayview Police Station, located at 201 Williams Avenue near Third Street. Police operating from this station provide service to the southeastern part of the City, extending along the eastern edge of McLaren Park to the Bay and south from Channel Street to the San Mateo County line. The Bayview District is one of the largest of San Francisco's ten police districts (covering about 18 percent of the City's land area). Refer to Figure III.O-1 (Southeast San Francisco Fire and Police Stations) for the SFPD station locations. The SFPD leases space on Parcel D-1 in Building 606 as a crime laboratory.

The Bayview District is currently divided into five sectors. The sectors are generally divided along Third Street, US-101 and other major roadways in the district. The two sectors that cover the Project site are located east of Third Street and extend from the San Mateo County line north to the Islais Creek channel and are generally divided north/south by Palou Avenue. The three remaining sectors are west of Third Street between Third Street and US-101, and generally divided north/south by Cesar Chavez Street and 24th Street. The last sector is located in the southwest quadrant of the intersection of US-101 and I-280 (Figure III.O-1).

FIGURE III.O-1

SOUTHEAST SAN FRANCISCO FIRE AND POLICE STATIONS

Police Operations

Four basic activities account for police services: responding to citizens' requests for service; initiating activities designed to promote order and detect or deter criminal behavior; conducting administrative tasks; and engaging in community policing (attending community meetings; working with community groups, businesses, schools, and other government agencies to prevent and control crime violence and disorder; meeting informally with residents and business people; working on problem solving projects). An organizational assessment of the SFPD, completed in December 2008, recommended a structure for allocating patrol officers' time among those activities.[906] Findings from the study indicate that, in 2007, the proportion of time spent on calls for service varied between 30.0 percent and 50.7 percent among San Francisco's 10 police districts. Citywide, the average was 42.9 percent; in the Bayview District, it was 48.3 percent.

Current Police Activity

Criminal incidents recorded by the SFPD are organized according to the severity of the crime. Part I crimes include aggravated assault, arson, auto boosting, burglary, homicide, larceny, motor vehicle theft, rape, and robbery. Part II crimes range from carrying weapons to receiving stolen property; they include embezzlement, forgery, other (non-aggravated) assaults, disorderly conduct, sex offenses, and others. According to SFPD records, a total of 3,862 Part I crimes were reported in the Bayview District in 2007. These incidents accounted for approximately 9 percent of Citywide Part I crimes (43,690 incidents reported in total). A total of 4,991 Part II crimes were reported in the Bayview District in 2007, or about 11 percent of Citywide Part II crimes (46,822 incidents in total).[907] For comparison, based on the 2000 Census data,[908] the Bayview District accounted for approximately 8 percent of the total City population (60,301 residents in Bayview as compared with 774,385 San Francisco residents)[909] and about 18 percent of the City's land area.[910]

Response Time

The type of police response required varies according to the nature and urgency of the call. Calls for services are categorized as Priority A, B, and C. Priority A calls are of the highest priority, Priority B calls are second in priority, and Priority C calls are the third level of priority. The 2007 Citywide average response times were reported in the *San Francisco Police Department District Station Boundaries Analysis* (*Boundaries Analysis*), and are identified in Table III.O-1 (Citywide and Bayview District Response Times [Minutes]) below. From 2008 to 2009, the overall average response time in the Bayview District has improved and is better than the citywide averages identified in 2007. Incident response times can vary depending on the physical location of patrol vehicles and officers in the district and the proximity to reported incidents.

---

[906] Police Executive Research Forum (PERF), *Organizational Assessment of the San Francisco Police Department: A Technical Report, Final Report*, December 2008.
[907] San Francisco Police Department, *2007 Annual Report*.
[908] While Section III.C (Population, Employment, and Housing) uses ABAG Projections, there is no comparable number for the "Bayview," thus Census data was used for this context.
[909] By 2005, the City population had grown to 783,441 according to 2005 population and households provided in a Memorandum from John Rahaim, Director of Planning, San Francisco Planning Department to Michael Carlin, Deputy General Manager, San Francisco Public Utilities Commissions, *Projections of Growth by 2030*, July 9, 2009. This still represents about eight percent of total City population.
[910] Public Safety Strategies Group (PSSG), *San Francisco Police Department District Station Boundaries Analysis*, p. 28, May 18 2008.

Incidents in progress and violent incidents require more immediate response than break-ins, acts of vandalism, or check scams that are discovered sometime after they occurred.[911] There are no adopted response time requirements for Priority A, B, or C calls.

Table III.O-1 Citywide and Bayview District Response Times (Minutes)

	2007 Citywide	*2008 Bayview*	*2009 Bayview*
Priority A	4:36	4:42	2:58
Priority B	8:02	8:31	6:28
Priority C	11:37	14:43	11:40

SOURCE: San Francisco Police Department (SFPD), Compstat-Bayview District, Response Times—June 2008 vs. June 2009 Dispatch to Arrival On-Scene, June 2009; Public Safety Strategies Group (PSSG), San Francisco Police Department District Station *Boundaries Analysis*, p. 44., May 18, 2008.

According to the SFPD 2007 Annual Report, the Bayview District received 6,148 Priority A calls, 10,784 Priority B calls, and 8,944 Priority C calls, for a total of 25,876 calls for service. In addition to calls for service, the Bayview District also dealt with a total of 110,781 on-view (i.e., on site) incidents that required an officer-initiated response.[912] In the Bayview District, pockets of increased police activity were identified directly north and west of HPS in the Hunters Point neighborhood, and in the Bayview and Potrero Hill neighborhoods.[913]

Incidents Associated with Type of Use

Land use and location affects the types of incidents that prompt calls for police assistance. Calls from residences can involve domestic disturbances, neighborhood disputes, burglaries, or drug sales, while calls from retail space can involve shoplifting and traffic incidents. Calls from office space can often involve burglaries (auto or personal items), and calls from entertainment uses depend largely on the type of tenants; busy nightclubs can have fights, and retail uses can have burglaries.[914]

The pattern of calls in existing retail areas provides an indication of the types of calls to expect in new retail areas. Call patterns near San Francisco Centre (the area within a 500-foot radius of Market and Fifth Streets in downtown San Francisco) and near Stonestown Galleria (the area within a half-mile radius of the retail center) are illustrative of the pattern associated with retail use. In 2007, the preponderance of calls centered on those retail concentrations related to larceny/theft (55 percent for San Francisco Centre and 37 percent for Stonestown). The second most frequent type of call was for non-criminal incidents (10 percent for San Francisco Centre and 7.4 percent for Stonestown).

As identified in the *Boundaries Analysis*, one factor impacting the demands for police services is personal and family income. In the Bayview District, similar to the Tenderloin, Mission, and Southern, Northern, and Central areas, which are areas that have 20 percent to 50 percent of the population living below the poverty level, there is a consistently recorded higher need for police services.[915]

915 Public Safety Strategies Group (PSSG), *San Francisco Police Department District Station Boundaries Analysis*, p. 29, May 18, 2008.

Staffing

In 2008, citywide, the Police Department had 2,449 budgeted positions for uniformed officers, of which 2,374 were filled, which represents approximately 97 percent of budgeted positions.[916] In 2005, the SFPD had a total of 2,033 sworn officers.[917][918]

Each of the City's ten district stations is staffed by members of the Patrol Division, which, together with the Traffic Division, make up the Field Operations Bureau. The Patrol Division, supported by Field Operations Bureau staff, is responsible for community policing throughout San Francisco by car and on foot. Bayview Station personnel include command staff, administrative officers, and patrol officers. In the first half of 2009, the staff of sworn officers at the Bayview Station ranged from 138 to 148 officers depending on new recruit levels and other variables.[919] Officers are assigned by sector, and the number of officers on patrol varies by shift, with the shifts staggered throughout the day; each sector in Bayview is staffed with 12 officers at all times.[920]

The SFPD also provides a "housing team" at the Alice Griffith public housing facility, which is located on the Project site. Citywide, housing teams are provided at each public housing facility.[921] In April 2009, the San Francisco Housing Authority (SFHA), in collaboration with the SFPD, implemented a Housing Liaison Program that provides supplemental law enforcement services to several large family developments, including the Alice Griffith public housing facility. Since the program was initiated in 2004 and covered select housing sites (not including Alice Griffith until 2009), the SFHA has experienced a reduction in violent crime.[922] The housing team at Alice Griffith consists of four officers; two per shift for two 12-hour shifts, seven days per week. During the shift officers must spend at least 50 percent of their time on foot, become involved with youth at the site, and officers are not called from their community policing assignments unless there is an emergency.[923] The presence of this housing team does not preclude the presence of a patrol car through the area, and the Bayview Station still responds to calls for service from the housing site if necessary.[924]

Additional officers are stationed in Candlestick Park on football game days, supplementing officers on regular duty assignments. The Bayview Station provides two officers to assist in traffic control and security

923 San Francisco Housing Authority (SFHA), Resolution Authorizing the Executive Director to Enter Into a One year Memorandum of Understanding Between the San Francisco Housing Authority and the San Francisco Police Department for Supplement Law Enforcement Services in an Amount not to Exceed $650,000, April 13, 2009.
924 PBSJ Meeting with SFPD on April 22, 2008.

during games. The balance of the coverage, generally from 18 to 22 off-duty officers, is assigned through the SFPD Homeland Security Unit. They are paid at overtime rates to work inside the stadium, patrol the parking lots, or assist with traffic control in the vicinity of the stadium. The cost of service is currently borne by the 49ers.[925]

Facilities

The Bayview Station opened in February 1997. The station is located about one mile west of Candlestick Point, and is about two miles from the northwest-most portion of HPS Phase II (refer to Figure III.O-1). The Bayview Station has approximately 16,000 square feet of interior space and an estimated 6,000-square foot surface parking lot.

A review of district police stations has recently been conducted as part of an evaluation of the boundaries of SFPD district stations. The *Boundaries Analysis* prepared by the Public Safety Strategies Group (PSSG) in 2008 made several relevant findings for this EIR analysis:

1. There is an immediate need for two new stations for the Central and Southern Districts, and the remaining eight stations [including the Bayview Station] do not meet the needs of effective police operations.
2. There are clear and longstanding areas of crime in the northeast and middle area of the City.
3. Workload distribution is not well balanced among the district stations.[926]

One of the results of the *Boundaries Analysis* is to recommend a 5-district system rather than the current 10 districts. While two new stations are identified as being needed in other areas of the City, the Bayview Station is identified for reorganization and reconfiguration to better utilize wasted and unused space and to provide structured parking to meet long-term operational needs and to accommodate additional officers.

According to the *Boundaries Analysis*, crime in the City is not associated with increases in population per se, or with increased commercial, entertainment, or office uses. Crime in the City has been remarkably stable for the 2002–2007 period, along with a stable number of police officers. New ways of policing are required in longstanding crime areas. [927]

III.O.3 Regulatory Framework

Federal

There are no federal police services regulations applicable to the Project.

State

There are no state police services regulations applicable to the Project.

---

[927] The Public Safety Strategies Group (PSSG), *San Francisco Police Department District Station Boundaries Analysis,* Table 2, p. 20, May 13, 2008.

Local

There are no local police services regulations applicable to the Project.

III.O.4 Impacts

Significance Criteria

The City and Agency have not formally adopted significance standards for impacts related to police services, but generally consider that implementation of the Project would have significant impacts if it were to:

O.a Result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, [or the] need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for police protection

Analytic Method

Impacts on police protection services are considered significant if an increase in population or development levels would result in inadequate staffing levels, response times, and/or increased demand for services that would require the construction or expansion of new or altered facilities that might have an adverse physical effect on the environment. A significant impact would occur if the Project generated the need for additional officers that could not be accommodated at the existing Bayview Station and would require the construction or expansion of a new facility in the Bayview District. This methodology for assessing impacts on police services was determined through interviews with SFPD staff, as well as communications with PSSG, a consulting firm hired by the SFPD to access facilities needs.

Additionally, the Project's potential contribution to cumulative land use impacts is evaluated in the context of existing, proposed, and reasonably foreseeable future development expected in the Project vicinity.

Construction Impacts

Impact PS-1: Police Protection during Construction

Impact PS-1 **Construction activities associated with the Project would not result in a need for new or physically altered facilities in order to maintain acceptable service ratios, response times, or other performance objectives for police protection. (Less than Significant with Mitigation) *[Criterion O.a]***

Construction activities could result in increased demand for police services if construction activities cause traffic conflicts requiring SFPD response. Access to the Project site during construction would be maintained by implementation of a construction management traffic plan (CMTP), as required by mitigation measure MM TR-1. The CMTP would provide necessary information to various contractors and agencies as to how to maximize the opportunities for complementing construction management measures and to minimize the possibility of conflicting impacts on the roadway system, while safely accommodating the traveling public in the area. The program would supplement and expand, rather than modify or supersede any manual, regulations, or provisions set forth by SFMTA, DPW or other City

departments and agencies. A cohesive program of operational and demand management strategies designed to maintain acceptable levels of traffic flow during periods of construction activities in the Bayview Hunters Point area would be implemented. These could include construction strategies, demand management strategies, alternate route strategies, and public information strategies.

Construction activities also could increase demand for SFPD services if the site is not adequately secured, providing increased opportunity for criminal activity. To ensure adequate site security, mitigation measure MM PS-1 would require the Project Applicant to provide security during project construction.

MM PS-1 *Site Security Measures During Construction. During site preparation and in advance of construction of individual buildings, fencing, screening, and security lighting shall be provided by the Project Applicant. During non-construction hours the site must be secured and locked, and ample security lighting shall be provided.*

Through implementation of the security measures required by mitigation measure MM PS-1, impacts to the SFPD would be considered less than significant.

Operational Impacts

Impact PS-2: Police Protection during Operation

Impact PS-2 **Implementation of the Project would not result in a need for new or physically altered facilities beyond those included as part of this Project in order to maintain acceptable service ratios, response times, or other performance objectives for police protection. (Refer to Sections III.D [Transportation and Circulation], III.H [Air Quality], III.I [Noise], III.J [Cultural Resources and Paleontological Resources], III.K [Hazards and Hazardous Materials], and III.M [Hydrology and Water Quality]) *[Criterion O.a]***

Evaluating the need for increased SFPD staff when new development is planned involves considering the size, location, and character of the new development. In most instances, development within San Francisco occurs within a fully developed and urban area, and the incremental increase in service area or service requirements associated with any one project is nominal.

However, in this instance, the Project site is mostly underutilized—portions of HPS are secured, and Candlestick Park stadium is quiet except for game days. The *Boundaries Analysis* shows that crime in the Bayview neighborhood is centered on Third Street at Palou and Third Street, south of Gilman. [928] The Project proposes development that would result in a new resident population of 24,465 (resulting from 10,500 housing units) and about 10,730 jobs (refer to Section III.C [Population, Housing, and Employment]). Based on the proposed development, the resident and worker population of the Project site at full build-out would be 35,195.[929] An increase in daytime population of about 34,000 at the Project

[928] The Public Safety Strategies Group (PSSG), *San Francisco Police Department District Station Boundaries Analysis,* Table 2, p. 20. May 13, 2008.

[929] Calculated as the combined total of a resident population of 24,465 and a worker population of 10,730. This is a conservative estimate since it is not likely that the entire resident population and daytime population would be on site at the same time. For this same reason, a separate calculation of the visitor population is not included, this would overestimate the potential daytime population.

site would require a different service delivery. Patrolling this new area and responding to calls would require at the least a redeployment of police services within the Bayview District, or within a wider area given the current recommendations for redistricting. With Mission Bay, a relatively recent example of a "city within a city," the SFPD are investigating a potential new location as their headquarters.[930]

Impacts on police protection services are considered significant if an increase in population or development levels would result in inadequate staffing levels (as measured by the ability of the SFPD to respond to call loads) and/or increased demand for services that would require the construction or expansion of new or altered facilities that might have an adverse physical effect on the environment.

To estimate personnel requirements for new projects, the SFPD considers the size of the incoming residential population and the expected or actual experience with calls for service from other potential uses of the site. Any potential increase in staffing at the SFPD Bayview Station would be expected to take place over time throughout the Project development period with the incremental addition of new housing and new non-residential building space and their occupancy.[931]

- From 2011 to 2017, demolition and abatement activities would occur on HPS Phase II as this is where most of the initial development would occur; the construction of a new 49ers stadium would occur between 2014 and 2017. Aside from earlier demolition and replacement of Alice Griffith housing, most construction at Candlestick Point would occur between 2017 and 2031. The first ten years of development would not see much of an increase in police requirements for service, as the 49ers stadium would replace similar uses on Candlestick Point. As addressed in Impact PS-1, security of the construction areas would be the responsibility of the Applicant. Between 2019 and 2032, as new residential and non-residential uses come online, there would be an increased need for police protection services.

  Although the City has no adopted staffing ratio, the existing "level of service" at the SFPD can be determined by comparing citywide police force staffing[932] to total City population (including both residents and workers). As shown in Table III.O-2 (Citywide Number of Police Officers and Estimated Project Site Demand), using a total City population for San Francisco of 1,351,469 and a police department staffing level of 2,033 in 2005 (consistent with population and employment data used in Table III.C-1 [Existing Population (2005)] and Table III.C-3 [Existing Employment (2005)] of Section III.C), a citywide ratio of 1 officer per 665 people was calculated.[933] This ratio when applied to the total projected resident and employee population of the Project site at build-out, results in a potential increase of 53 police personnel to provide a comparable level of service in the Bayview District. Refer to Table III.O-2.

---

930 "Mission Bay May House Police Hub", San Francisco Examiner, February 24, 2009. Available at http://www.sfexaminer.com/local/Mission-Bay-may-house-police-hub-40203627.html.
931 PBSJ Meeting with SFPD on April 22, 2008.
932 Using a Citywide police force staffing number accounts for the mixed-use nature of the Project, which would include a substantial daytime and resident or nighttime population.
933 City population was calculated as a 2005 population of 799,302 plus 2005 employment of 552,167; refer to Table III.C-1 (Existing Population [2005]) and Table III.C-3 (Existing Employment [2005]) of Section III.C (Population, Housing, and Employment).

Table III.O-2 Citywide Number of Police Officers and Estimated Project Site Demand

		Population	*Police Officers*
Citywide (2005)			
Residents		799,302	
Employees		552,167	
	Total	***1,351,469***	***2,033***
Ratio (officer to population)		1:665	
Project (2029)			
Residents		24,465	
Employees		10,730	
	Total	***35,195***	***53***
Ratio (officer to population)		1:665	

SOURCE: The population and households data reported for San Francisco is 2005 data provided in a Memorandum from John Rahaim, Director of Planning, San Francisco Planning Department to Michael Carlin, Deputy General Manager, San Francisco Public Utilities Commissions, *Projections of Growth by 2030*, July 9, 2009.; SFPD 2005 total staffing: PSSG District Station *Boundaries Analysis*, 2008; Proposed population and employment: Section III.C (Population, Housing, and Employment).

The SFPD evaluates the need for additional officers by sector, and not station or district needs. The Project site is located in two of the five sectors within the Bayview District, both of which have been identified as high demand areas. While it is unlikely that 53 new officers would be needed at the outset of project development as development would occur over a 20-year time period, some redistribution of the police presence in the southeastern portion of the City would be warranted by Project development, as described above.

While staffing increases, in and of themselves, would not create a significant environmental impact, the construction of new facilities to serve the additional 53 police officers could create significant environmental impacts. Additional SFPD personnel of this magnitude (i.e., 53 officers) needed to serve the Project would require a station from which to operate. Even if the existing Bayview Station were to be reconfigured and if the existing civilian personnel who occupy the station were to be moved to another facility, the existing space would not be adequate to support 53 new police officers. The exact amount of space that would be needed has not yet been determined. However, using an estimate of 110 square feet per person,[934] the additional 53 police officers would require approximately 6,000 square feet of interior building space. Additional space would be required for staff and visitor parking. According to SFPD, there is limited excess capacity at the existing Bayview Station, and the station would not be able to accommodate all 53 of the additional police officers without the reconfiguration and expansion of the existing station or the construction of a new facility.[935] In addition, the current surface parking lot is not adequate for existing personnel. Structured parking could be provided on the existing parking site.

Currently, the SFPD has no plans for expansion of its Bayview Station. According to the *Boundaries Analysis*, Bayview Station is not among the priorities for replacement, expansion, improvement, or correction of current deficiencies. However, according to PSSG, there is a considerable amount of wasted or unused space

[934] The Bayview Station is similarly sized to the other stations in the City, each of which is targeted for reconfiguration, and is approximately 16,000 gsf, and the capacity is about 140 officers, resulting in about 114 sf per officer.
[935] Personal communication, John Loftus, Captain, Bayview District Station to Allison Wax, PBS&J, August 31, 2009.

at the Bayview Station that could be reconfigured to accommodate additional officers.[936] If the SFPD determines that the reconfiguration of the Bayview Station would not be sufficient to accommodate additional officers, a new station or facility of approximately 6,000 square feet (sf) could be constructed within the Project site on land designated for community-serving uses. As part of the Project, up to 100,000 gross square feet (gsf) divided equally between Candlestick Point and HPS Phase II would be designated for community-serving uses, such as fire, police, healthcare, day-care, places of worship, senior centers, library, recreation center, community center, and/or performance center uses. These uses have been anticipated as part of the Project, and the impacts of their construction are evaluated in this EIR. As such, in the event that a new police facility (counter, storefront, or other configuration) should be constructed on the Project site, construction of the new facility has been addressed in this EIR. With the construction of a new facility or a suitable retrofitting or expansion of the Bayview Station, the SFPD would have ample space to accommodate the additional police officers needed to maintain the SFPD's existing level of service. This analysis assumes that staffing associated with the Project could be accommodated within the Project site.

Construction activities associated with the proposed public facilities, which could include a potential 6,000 square foot building space for new police officers, are considered part of the overall Project. A discussion of project-related construction impacts, including those associated with the construction of public facilities, is provided in the applicable sections of this EIR, including Section III.D (Transportation and Circulation), Section III.H (Air Quality), Section III.I (Noise), Section III.J (Cultural Resources and Paleontological Resources), Section III.K (Hazards and Hazardous Materials), and Section III.M (Hydrology and Water Quality). Construction impacts would be temporary. While it is likely that construction of the various public facilities would not result in significant impacts (either individually or combined), construction of the entire development program, of which the public facilities are a part, would result in significant and unavoidable impacts related to construction noise and demolition of an historic resource; all other construction-related impacts would be less than significant (in some cases, with implementation of identified mitigation). Refer to Section III.D, Section III.H, Section III.I, Section III.J, Section III.K, and Section III.M for the specific significance conclusions for construction-related effects.[937]

- As the Project identifies community service use areas that could be used for police services, and as police services are not tied to a specific station, the SFPD would be able to maintain acceptable levels of police service during operation of the Project. While the development of the Project may require new or physically altered police facilities in order to maintain acceptable police services, the potential impacts associated with the construction of a new facility have been addressed in this EIR and would not require further environmental review. As such, no mitigation is required.

Cumulative Impacts

The geographic context for the analysis of cumulative impacts associated with police protection is the City of San Francisco. The past and present development in the City is described in the Setting section of this chapter,

[936] PBSJ Meeting with SFPD on April 22, 2008.
[937] The impact statements provided in each technical section of the EIR differentiate between construction impacts and operational or development impacts, and all identified mitigation measures are contained in the impact analysis. In addition, Table ES-2 in the Executive Summary of this EIR also summarizes all impact statements, the level of significance before mitigation, any identified mitigation measures, and the level of significance after mitigation.

representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable future development forecasts are based on projections of future growth and take into account projects going through the entitlement process. The City of San Francisco provides public services within the City's boundaries.

Development of cumulative projects within the City of San Francisco would result in increased population and employment-generating uses, based on recent projections, and associated increased demand for police protection. The Planning Department routinely prepares projections for the purposes of analyzing impacts of plans and projects undergoing the environmental review process. The Planning Department's recently completed projections, capturing citywide growth expectations by 2030.[938] It should also be noted that the projections also took into account existing conditions and other major projects currently in various stages of the entitlement process, including Executive Park, Visitacion Valley, Hunters View, as well a Treasure Island, Park Merced projects, and the Project. Development projections estimate an increase of 61,814 households, 133,359 persons, and 195,010 jobs from 2005 to 2030, either the latest year for which projections have been formulated or the closest year to Project build-out for projections which extend in five-year increments beyond 2030, consistent with other projections in this EIR.

Citywide, the Police Department has 2,449 budgeted positions for uniformed officers, of which 2,374 are currently filled, which represents approximately 97 percent of budgeted positions. A review of district police stations has recently been conducted as part of an evaluation of the boundaries of SFPD district stations. The *Boundaries Analysis* report identifies improvement needs at most existing stations, noting that the stations are either at capacity or too small for the number of personnel assigned, storage is lacking, locker rooms are inadequate, and technology is outdated and/or non-existent. The report further identifies that most of the stations, despite being fairly new or updated, do not fully meet the needs of the SFPD.[939] Two stations (Central and Southern) are recommended for replacement. However, while the Police Department considers population growth projections in its annual budgeting process to determine equipment and staffing needs for the coming year, it is possible that cumulative growth in the City could exceed the capacity of existing or planned staffing and facility improvements, and could require construction of one or more stations, resulting in a significant impact.

The report does not identify the Bayview station for replacement, expansion, or improvement; correction of current deficiencies at this station is not among the priorities suggested in the *Boundaries Analysis* report. No specific Bayview station needs have been identified for early action. The report does identify the potential for reconfiguration of the existing station and provision of structured parking to meet long-term operational needs at the Bayview station. Project changes in residential and non-residential development levels and land use intensity would take place over a period of years and could, over time, potentially add to SFPD staffing needs. In particular, based on existing call levels to other commercial and retail centers in the City, the Project would be likely to result in an increased number of similar calls for service. As noted, above, an increase in the Bayview station staff to respond to demand from new development would be expected to take place throughout the development period with the addition of new housing units and new non-residential building space and their occupancy. Demand for increased staffing, in and of itself, would not constitute a significant environmental impact. The need for increased staffing, however, could lead to the need for expanded or replacement facilities. Inasmuch as the increased staffing demand could

[938] Correspondence from John Rahaim, Director of Planning, to SFPUC dated July 9, 2009.
[939] Ibid. May 13, 2008, pp. 20 and 27.

be accommodated by a reconfigured Bayview Station and/or a new facility within the Project site, construction activities associated with proposed public facilities are considered part of the overall Project. A discussion of project-related construction impacts, including those associated with the construction of public facilities, is provided in the applicable sections of this EIR, including Section III.D, Section III.H, Section III.I, Section III.J, Section III.K, and Section III.M. Construction impacts would be temporary. While it is likely that construction of the various public facilities would not result in significant impacts (either individually or combined), construction of the entire development program, of which the public facilities are a part, would result in significant and unavoidable impacts related to construction noise and demolition of an historic resource; all other construction-related impacts would be less than significant (in some cases, with implementation of identified mitigation). Refer to Section III.D, Section III.H, Section III.I, Section III.J, Section III.K, and Section III.M for the specific significance conclusions for construction-related effects.[940] Therefore, because the Project would require new or physically altered police facilities in order to maintain acceptable police services, the Project would make a cumulatively considerable contribution to a potential significant cumulative impact on police services. The Project's cumulative impact would be significant.

Fire and Emergency Medical Services

III.O.5 Setting

The San Francisco Fire Department (SFFD) is responsible for protecting life and property throughout San Francisco from fires, natural disasters, and hazardous materials incidents, and by providing emergency medical services.[941] The SFFD has forty-three station locations distributed throughout the City of San Francisco.[942] Staffing at each station is determined based on the types of firefighting apparatuses each station maintains. Engines are staffed with one officer and three firefighters, and trucks are staffed with one officer and four firefighters. The terms "fire engine" and "fire truck" represent different types of fire fighting apparatus. Ambulances are staffed with one paramedic specialist who provide pre-hospital advanced medical and trauma care. Total daily staff for all SFFD stations is currently 315, and the current shift ratio for SFFD is 4.25 shifts per day in 2008.[943] Using this shift ratio and the number of daily staff, approximately 74 staff persons are on duty per shift throughout all of the City's 43 stations.

Of the 43 SFFD fire stations located throughout the City, five of these stations are located in southeast San Francisco. No SFFD stations are located within the Project site itself (refer to Figure III.O-1 for the SFFD station locations). Stations east of US-101 in this part of the City include the following:

- Station 9 is located at 2245 Jerrold Avenue between Napoleon Street and Upton Street

[940] The impact statements provided in each technical section of the EIR differentiate between construction impacts and operational or development impacts, and all identified mitigation measures are contained in the impact analysis. In addition, Table ES-2 in the Executive Summary of this EIR also summarizes all impact statements, the level of significance before mitigation, any identified mitigation measures, and the level of significance after mitigation.
[941] San Francisco Fire Department Website, Mission Statement, The mission statement also includes fire prevention education and goals for the work environment. http://www.sfgov.org/site/sffd_index.asp.
[942] San Francisco Fire Department Website. Station Locations.
http://www.sfgov.org/site/sffd_page.asp?id=57819#stations (accessed on September 11, 2009).
[943] PBSJ Meeting with San Francisco Fire Department on July 8, 2008.

- Station 17 is located at 1295 Shafter Avenue at the corner of Ingalls Street
- Station 25 is located at 3305 Third Street, between the bridge over the Islais Creek Channel and Cargo Way

Stations west of US-101 in this part of the City include the following:

- Station 42 is located at 2430 San Bruno Avenue between Silver Avenue and Silliman Street
- Station 44 is located at 1298 Girard Street at the corner of Wilde Avenue, about a half block west of San Bruno Avenue

The SFFD target response time goal for Code 1 (non-emergency) calls is 8 minutes, for Code 2 (non life-threatening fire and medical emergencies) calls the response time goal is 20 minutes, and for Code 3 (life-threatening fire and medical emergencies) calls, the highest response priority, the response time goal is 4.5 minutes.[944] When responding to Code 3 calls, responding vehicles use flashing lights and sirens and cross intersections against control lights. The SFFD is currently in the 90th percentile for attainment of all the department's response time goals. Target response times are considered in the planning and siting of new fire stations within San Francisco.[945]

Stations located east of US-101 respond to calls within the Bayview Hunters Point neighborhood. The stations west of the US-101 may also respond; however, the freeway creates an obstruction that makes access to areas east of the freeway more difficult from this location. For Station 42, the closest cross-freeway route is the Silver Avenue undercrossing. From Station 44, the Paul Avenue undercrossing is reached by going north on San Bruno Avenue to Mansell Street and then to Paul Avenue, or the Bayshore Boulevard/3rd Street overcrossing can be reached by going south on San Bruno Avenue to Bayshore Boulevard. Table III.O-3 (Fire Stations in Southeast San Francisco) lists the SFFD stations that serve the BVHP area and the Project site, and the primary fire and emergency medical services they provide.

Table III.O-3 Fire Stations in Southeast San Francisco

Station	*Location*	*Nearest Major Street*	*Paramedic Capable*	*Equipment*	*# of personnel per shift*

17	1295 Shafter Ave	Ingalls St.	Yes	Engine, Ladder Truck	9
25	3305 Third St.	Cargo Way	Yes	Engine	4
42	2430 San Bruno Ave.	Silver Ave.	Yes	Engine	4
44	1298 Girard St.	San Bruno Ave.	Yes	Engine	4

SOURCE: SFFD. Captain Andy Zanoff, SFFD, personal communications to Mundie & Associates, May 2009; Anne Tam, SFFD, verbal communication with Allison Wax, PBS&J on September 2, 2009.

The number of personnel per shift depends on the equipment at each station. Fire engines require four staff per shift, ladder trucks require five staff per shift, Battalion Chief requires one staff per shift, and ambulances require one staff per day.

An engine carries one officer (a captain or a lieutenant) and three firefighters, one of whom is either a designated Emergency Medical Technician (BLS/basic life support) or a Paramedic (ALS/advanced life support).

945 Ibid.

Travel times from fire stations near the Candlestick Point and HPS Phase II sites for an ordinary driver are shown in Table III.O-4 (Access to Candlestick Point and HPS Phase II from Nearby Fire Stations). Because the travel time information presented in Table III.O-4 represents an estimated travel time for an ordinary driver, it is a conservative (i.e., high) estimate of response time for emergency vehicles. Unlike an ordinary driver, an emergency vehicle can stop other traffic by the use of emergency sirens and can pass through intersections with traffic signals at reduced speeds even when receiving a red signal indication. Therefore, the time required to travel to the Project site for an emergency would be reduced, and would be consistent with City response times.

Table III.O-4 Access to Candlestick Point and HPS Phase II from Nearby Fire Stations

a. Distances reported are from the indicated station to the Alice Griffith housing complex.

Water supply for fire suppression in San Francisco is provided by an auxiliary water supply system (AWSS). Water for the AWSS is distributed through a network of pipes drawing water from a collection of reservoirs and pumping stations throughout the City. The Project would extend the AWSS to the Project site. Refer to Section III.Q (Utilities) for additional detail about water infrastructure, including the AWSS.

III.O.6 Regulatory Framework

Federal

There are no federal fire protection regulations applicable to the Project.

State

California Fire Code

State fire regulations are set forth in Sections 13000, *et seq*. of the *California Health and Safety Code*, which include regulations concerning building standards (as also set forth in the *California Building Code*), fire protection and notification systems, fire protection devices (such as extinguishers and smoke alarms, high-rise building and childcare facility standards), and fire suppression training.

Local

San Francisco Fire Code

The *San Francisco Fire Code* incorporates by reference the *California Fire Code*, with certain local amendments. The *San Francisco Fire Code* was revised in 2007 to regulate and govern the safeguarding of life and property from fire and explosion hazards arising from the storage, handling, and use of hazardous substances, materials and devices, and from conditions hazardous to life or property in the occupancy of buildings and premises; and to provide for the issuance of permits, inspections, and other SFFD services; and the assessment and collection of fees for those permits, inspections, and services. The SFFD reviews building plans to ensure that fire and life safety is provided and maintained in the buildings that fall under its jurisdiction. SFFD plan review applies to all of the following occupancy types:[946]

- Assembly occupancies (including restaurants and other gathering places for 50 or more occupants)
- Educational occupancies (including commercial day care facilities)
- Hazardous occupancies (including repair garages, body shops, fuel storage, and emergency generator installation)
- Storage occupancies where potential exists for high-piled storage as defined by Fire Code
- Institutional occupancies
- High-rise buildings of all occupancies
- Residential Occupancies, such as hotels, motels, lodging houses, residential care facilities, apartment houses, small-and large-family day care homes, and R-1 artisan buildings (excluding minor residential repairs such as kitchen and bath remodeling and dry rot repair)
- All fire alarm and fire suppression systems

In coordination with the San Francisco Department of Building Inspection (DBI), the SFFD conducts plan checks to ensure that all structures, occupancies, and systems outlined above are designed in accordance with the *San Francisco Building Code*.

Section 511 (Local Fire Safety Feature Requirements) of the *San Francisco Fire Code* requires that buildings 200 feet or more in height must provide at least one elevator approved by the Fire Department for firefighter use under fire conditions. The section also requires that for buildings having floors used for human occupancy located more than 75 feet above the lowest level of Fire Department vehicle access, an air replenishment system shall be installed to provide a means for firefighters to refill air bottles for self-contained breathing apparatus (SCBA) through a permanently installed piping distribution system. The system shall be tested and maintained pursuant to the Fire Department Administration Bulletin.

III.O.7 Impacts

Significance Criteria

The City and Agency have not formally adopted significance standards for impacts related to fire services, but generally consider that implementation of the Project would have significant impacts if it were to:

[946] San Francisco Fire Department, *Plan Check,* 2009. http://www.sfgov.org/site/sffd_page.asp?id=57395.

O.b Result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, [or the] need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives

Analytic Method

Impacts on fire protection services are considered significant if an increase in population or development levels would result in inadequate staffing levels, response times, and/or increased demand for services that would require the construction or expansion of new or altered facilities that might have an adverse physical effect on the environment. A significant impact would occur if additional calls anticipated to result from the Project could not be accommodated within SFFD's target Code 3 response time of 4.5 minutes. Code 1 and Code 2 is for non-emergency calls with a response time of 8 minutes and 20 minutes, respectively, and are not emergency-response related.

The SFFD's response time could be affected by inadequate staffing levels caused by increases in demand. An increase in population or development may result in the need for additional fire protection personnel. The methodology for assessing impacts on fire protection and emergency medical services was determined through interviews with SFFD staff, who reviewed projected response times and development intensities at the Project site against the SFFD's target Code 3 response time of 4.5 minutes to determine whether additional staffing and therefore new facilities would be needed to provide adequate future service.[947] This information was then applied to the Project's potential increase in response time.

Additionally, the Project's potential contribution to cumulative land use impacts is evaluated.

Construction Impacts

Impact PS-3: Fire Protection and Emergency Medical Services during Construction

Impact PS-3 **Construction activities associated with the Project would not result in a need for new or physically altered facilities in order to maintain acceptable response times for fire protection and emergency medical services. (Less than Significant with Mitigation) *[Criterion O.b]***

During construction of the Project, emergency access to the Project site would be maintained through compliance with the Construction Transportation Management Plan (CTMP) prepared for the Project, as required by mitigation measure MM TR-1. Compliance with the CTMP would ensure that access to the Project site is not obstructed during construction activities. The CTMP would provide necessary information to various contractors and agencies as to how to maximize the opportunities for complementing construction management measures and to minimize the possibility of conflicting impacts on the roadway system, while safely accommodating the traveling public in the area. The program would supplement and expand, rather than modify or supersede any manual, regulations, or provisions set forth by SFMTA, DPW, or other City departments and agencies. A cohesive program of operational and demand

[947] PBSJ Meeting with San Francisco Fire Department on July 8, 2008.

management strategies designed to maintain acceptable levels of traffic flow during periods of construction activities in the Bayview Hunters Point area would be implemented. These could include construction strategies, demand management strategies, alternate route strategies, and public information strategies. As such, construction of the Project would not impact SFFD response times, nor would it require expansion of or replacement of SFFD stations. Impacts to the SFFD would be considered less than significant.

Operational Impacts

Impact PS-4: Fire Protection and Emergency Medical Services during Operation

Impact PS-4 **Implementation of the Project would not result in a need for new or physically altered facilities beyond those included as part of this Project in order to maintain acceptable response times for fire protection and emergency medical services. (Refer to Sections III.D [Transportation and Circulation], III.H [Air Quality], III.I [Noise], III.J [Cultural Resources and Paleontological Resources], III.K [Hazards and Hazardous Materials], and III.M [Hydrology and Water Quality]) *[Criterion O.b]***

The Project would add 10,500 residential units and substantially increase employment-generating uses, resulting in an employment population of 10,730. The increase in the residential and daytime population (for a total population of 35,195), combined with an increase in the intensity of physical development on the Project site, would result in new demand for fire protection and emergency medical services.

Building Safety

All new buildings must meet standards for emergency access, sprinkler, and other water systems, as well as all other requirements specified in the *San Francisco Fire Code*, which would help to minimize demand for future fire protection services. In addition, all development, including high-rise residential buildings would be reviewed by DBI and the SFFD to ensure that structures are designed in compliance with the *San Francisco Fire Code*. Section 511.1 and Section 511.2 of the *San Francisco Fire Code* outlines specific requirements for high-rise (i.e., buildings above 200 feet) buildings, and would apply to the Project's proposed high-rise structures. All proposed structures exceeding 200 feet in height would be required to install at least one elevator approved by the Fire Department for firefighter use under fire conditions, and an air replenishment system would be required for buildings intended for human occupancy located more than 75 feet above the lowest level of Fire Department vehicle access. Plan review for structures at Candlestick Point and HPS Phase II for compliance with *San Francisco Fire Code* requirements would minimize the potential for fire-related emergencies by providing on-site protective features, reducing the demand for fire protection services at the Project site. In addition, as noted above, development of the Project would also include expansion of the AWSS to provide water infrastructure for firefighting activities. Refer to Section III.P for additional detail about the available water supply at the Project site and the proposed water infrastructure improvements, including the AWSS.

Response Time

As stated in Section III.O.5 (Setting), Stations 44 and 17 provide primary response to the Project site. Three additional stations located nearby could also respond to calls for service. Travel times from fire stations near Candlestick Point and HPS Phase II for an ordinary driver are shown in Table III.O-4, although it is likely that the time traveled from any of these stations would be reduced for emergency vehicles. The SFFD strives to maintain an average response time for fire and medical emergencies of 4.5 minutes, which may not be attainable when emergency vehicles are dispatched to the HPS Phase II site from any of the five stations. Travel times to the HPS Phase II site could take between 8 to 14 minutes based on an ordinary driver; and travel time to the Candlestick Point site could take over 4.5 minutes from Station 9 and Station 25. This estimate is based on the existing street grid to present a conservative (i.e., high) estimate of travel time to the Project site, which would be substantially different under Project conditions.

Candlestick Point

The travel time information represents an estimated travel time that an ordinary driver might experience on routes from existing SFFD stations to points within the Project site. Unlike an ordinary driver, an emergency vehicle can stop other traffic by the use of emergency sirens and can pass through intersections with traffic signals at reduced speeds even when receiving a red signal indication. In addition, Project conditions would include new roadway improvements (refer to Chapter II [Project Description]) that would speed access through and within the Project site. Therefore, the estimated time it takes for emergency vehicles to access the Project site is conservative (i.e., high), and it is likely that the time traveled to the Project site for an emergency would be reduced compared to an ordinary driver, and could be significantly reduced.

Existing SFFD facilities in the Bayview neighborhood would provide adequate response times to most points on Candlestick Point. Access to Candlestick Point would be a key factor in the ability of the SFFD to provide adequate fire protection and emergency medical services to this site. Roads providing access to Candlestick Point include Gilman Avenue, Jamestown Avenue, and Harney Way. SFFD personnel have reviewed the Project and concluded that no additional fire stations would be needed to serve Candlestick Point alone and emergency service can be provided within the average response time of 4.5 minutes, as shown on Table III.O-4.[948] Emergency access to Candlestick Point on game days would be provided via three primary routes: on the Harney Way/Arelious Walker Drive route from the south, emergency vehicles would be allowed to use the BRT-only lane; on Palou Avenue from the west; and from Innes Avenue on the north. No new or physically altered fire or emergency medical facilities would be required in order to maintain an acceptable level of service.

HPS Phase II

As shown in Table III.O-4, portions of the proposed development at HPS Phase II would be at a distance from existing fire stations including those most proximate to the site (Stations 44 and 17), and could take from 8 minutes to 14 minutes to access HPS Phase II. The SFFD strives to maintain a Code 3 emergency response time of 4.5 minutes, which may not be accommodated due to the distance of the nearest station and HPS Phase II. As such, a new fire station located in closer proximity to the Project site would be

[948] PBSJ Meeting with San Francisco Fire Department on July 8, 2008.

needed to ensure adequate response times for HPS Phase II. The SFFD does not consider response time to the furthest extent of the HPS Phase II site to be acceptable, given the density of proposed development and the distance for the nearest fire station.[949] SFFD staff concluded that a fire station would be needed at a site that would offer more rapid response to the HPS Phase II site. Initial SFFD recommendations for such a station included providing one engine (four staff), one truck (five staff), and one ambulance (staff requirements not indicated). Both Station 9 and Station 17 include one engine and one truck, and their approximate building size is 6,100 gsf and 6,000 gsf, respectively. Neither station includes an ambulance. A new approximately 6,000-gsf SFFD station (or larger if an ambulance were accommodated) could be accommodated on the Project site, on land designated for community-serving uses. As part of the Project, up to 100,000 gsf divided equally between Candlestick Point and HPS Phase II would be designated for community-serving uses, such as fire, police, healthcare, day-care, places of worship, senior centers, library, recreation center, community center, and/or performance center uses.

These uses have been anticipated as part of the Project and the impacts of their construction are evaluated in this EIR. Construction activities associated with proposed public facilities are considered part of the overall Project. A discussion of project-related construction impacts, including those associated with the construction of public facilities, is provided in the applicable sections of this EIR, including Section III.D, Section III.H, Section III.I, Section III.J, Section III.K, and Section III.M. Construction impacts would be temporary. While it is likely that construction of the various public facilities would not result in significant impacts (either individually or combined), construction of the entire development program, of which the public facilities are a part, would result in significant and unavoidable impacts related to construction noise and demolition of an historic resource; all other construction-related impacts would be less than significant (in some cases, with implementation of identified mitigation). Refer to Section III.D, Section III.H, Section III.I, Section III.J, Section III.K, and Section III.M for the specific significance conclusions for construction-related effects.[950] As such, the construction impacts associated with a new SFFD facility on the Project site have been addressed in this EIR. With the construction of a new SFFD facility located in closer proximity to HPS Phase II, emergency response times would be reduced due to the reduced distance that dispatched vehicles would be required to travel to access the Project site.

Game Day Access

The 49ers football stadium would require particular consideration and planning to ensure that adequate access is provided during athletic or other events. Those events result in higher than typical traffic, and high volumes of traffic put emergency vehicles in competition with civilian cars for traffic lanes. An access network capable of clearing lanes for emergency vehicles when needed would alleviate this potential problem. Prior to construction of new land uses at HPS Phase II, review of access strategies for game day and non-game day scenarios would be required pursuant to the SFFD's plan review requirements.[951]

---

[949] PBSJ Meeting with San Francisco Fire Department on July 8, 2008.

[950] The impact statements provided in each technical section of the EIR differentiate between construction impacts and operational or development impacts, and all identified mitigation measures are contained in the impact analysis. In addition, Table ES-2 in the Executive Summary of this EIR also summarizes all impact statements, the level of significance before mitigation, any identified mitigation measures, and the level of significance after mitigation.

[951] San Francisco Fire Department, Plan Check website. http://www.sfgov.org/site/sffd_page.asp?id=57395 (accessed August 2009).

As described in the Candlestick Point-Hunters Point Shipyard Phase II Development Plan Transportation Study (CHS Consulting, Fehr & Peers, and LCW Consulting, October 2009), the Project calls for a new Traffic Management Center, to be staffed by City employees, to dynamically monitor and operate traffic signals along primary ingress and egress routes to efficiently move traffic into and out of the area prior to and after games. In addition, similar to existing conditions, traffic control officers would be stationed at key locations to ensure efficient traffic movements.

Similar to existing conditions, the majority of stadium bound traffic would use a portion of US-101 to access the project site on game days. Traffic from the south would predominantly use northbound US-101 and access the site via Harney Way, while traffic from the north would predominantly use southbound US-101 and I-280 and access the site via Cesar Chavez Street, Cargo Way, Evans Avenue, and Innes Street. Some trips to the site would use Bayshore Boulevard or Third Street to access the area via Carroll Avenue, Gilman Avenue and Ingalls Street.

Prior to and after games in the proposed stadium, special measures (similar to those in place for existing football games) would be taken to allow the site's circulation system to accommodate unique game day traffic flows. Prior to games, the site's roadways would be geared towards inbound flow and after games the roadways would be geared towards outbound flow.

Vehicles accessing the new stadium from the south would use Harney Way. Harney Way would be configured to provide four inbound lanes (to the stadium) and one outbound lane between US-101 and Arelious Walker Drive. Arelious Walker Drive, between Harney Way and Crisp Road would provide four inbound lanes. Crisp Road would provide seven inbound lanes between Arelious Walker Drive and the new stadium. The lane configurations would be reversed for post-game conditions. Vehicles accessing the new stadium from the south, would be routed as described above to Crisp Road, where it would be channeled to a Ring Road on the southern portion of the stadium. Access to the internal parking aisles would be from the Ring Road.

Vehicles accessing the new stadium from the north would use Evans Avenue and Cargo Way. These inbound routes would merge at Hunters Point Boulevard/Jennings/Evans. From there, the inbound route along Hunters Point Boulevard and Innes Avenue would provide four inbound lanes and one outbound lane. The lane configurations along Hunters Point Boulevard and Innes Avenue would be reversed for post-game conditions.

On the Harney Way/Arelious Walker Drive route, emergency vehicles would be allowed to use the BRT-only lanes (the BRT-only lanes break off from the primary auto route and continue on Harney Way, east of Arelious Walker Drive, and on Egbert before reconnecting with Arelious Walker Drive immediately south of the Yosemite Slough bridge). Emergency vehicles would also be allowed to use Palou Avenue, which would be transit-only on game days. Both of these routes would be free of congestion, and would offer emergency vehicle access between regional facilities and Crisp Road. Emergency vehicles would be able to enter the stadium parking lot via Crisp Road. Emergency vehicles would also be able to use Innes Avenue, as there would be at least one lane in each direction on this route open to traffic. However, since immediately following games the outbound direction may be congested, this may not be as desirable a route as the Harney Way BRT lanes or Palou Avenue.

Conclusion

Construction of a new SFFD facility on land designated for community-serving uses on the Project site would allow the SFFD to maintain acceptable response times for fire protection and emergency medical services. Construction of 100,000 gsf of community facilities, which could include a new SFFD facility, has been included as a component of the Project. Therefore, while the development of the Project may require new or physically altered SFFD facilities in order to maintain acceptable fire protection and emergency medical services, the potential impacts associated with the construction of a new facility have been addressed in this EIR and would not require further environmental review.

Cumulative Impacts

The geographic context for the analysis of cumulative impacts associated with fire protection is the City of San Francisco. The past and present development in the City is described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable future development forecasts are based on projections of future growth and take into account projects going through the entitlement process. The City of San Francisco provides public services within the City's boundaries.

Development of cumulative projects within the City of San Francisco would result in increased population and employment-generating uses, based on recent projections, and associated increased demand for police protection. The Planning Department routinely prepares projections for the purposes of analyzing impacts of plans and projects undergoing the environmental review process. The Planning Department's recently completed projections, capturing citywide growth expectations by 2030.[952] The projections also took into account existing conditions and other major projects currently in various stages of the entitlement process, including Treasure Island, Park Merced projects, and the Project. Development projections estimate an increase of 61,814 households, 133,359 persons, and 195,010 jobs from 2005 to 2030, either the latest year for which projections have been formulated or the closest year to Project build-out for projections that extend in 5-year increments beyond 2030, consistent with other projections in this EIR.

Development of cumulative projects within the City of San Francisco would result in increased population and employment-generating uses, based on recent Planning Department projections, and increased demand for fire and emergency medical services. This increase in demand would potentially affect response times, requiring the construction of new facilities. This would also include increased demand for water and potential improvements in conveyance systems for firefighting purposes. The SFFD target response time goal for Code 3 life-threatening fire and medical emergencies, the highest response priority, is 4.5 minutes. This target response time is considered in planning and siting of new fire stations within the City.

All cumulative projects would be built to *San Francisco Fire Code* standards, which would help to minimize demand for future fire protection services. All development, including high-rise residential buildings up to 40 stories, would meet standards for emergency access, sprinkler and other water systems, and other requirements specified in the *San Francisco Fire Code*. Standards pertaining to equipment access would also be met. Plan review for proposed structures for compliance with *San Francisco Fire Code* requirements, to

[952] Correspondence from John Rahaim, Director of Planning, to SFPUC dated July 9, 2009.

be completed by DBI and the SFFD, would minimize fire-related emergency dispatches, reducing the demand for fire protection services. New or physically altered fire or emergency medical facilities could be required in order to maintain acceptable levels of service from cumulative development, and expansion of the water conveyance system could also be required. Because it is unknown the extent to which such facilities and systems would require expansion and whether such improvements would accommodate projected growth, this is a potentially significant impact.

Existing SFFD facilities in the Bayview neighborhood would provide adequate response times to most points within the Project site. SFFD staff, reviewing considerations of development types and distances, concluded that a fire station would be needed at a site that would offer more rapid response to the Project site. Recommendations for such a station included providing one engine (four staff), one truck (five staff), and one ambulance (staff requirements not indicated), in an approximately 6,000-gsf building. The SFFD land could be accommodated on the Project site. Since adequate response times would be ensured for the Project through provision of a new fire facility, the construction of which is evaluated and mitigated for in this EIR, the Project would not make a cumulatively considerable contribution to any potentially significant cumulative impact on fire and emergency medical services. The Project's cumulative impact would be less than significant.

Schools

III.O.8 Setting

The San Francisco Unified School District (SFSUD) oversees the public school system in San Francisco (K–12). The SFUSD is comprised of 37 preschools and 104 schools serving various grade levels (K–5, K–8, and 9–12). Based on data for the 2008/09 school year, there are approximately 56,000 students currently attending public schools in San Francisco (refer to Table III.O-5 [Existing Classroom Capacity and Enrollment, SFUSD, 2008]).[953] It is estimated that another 20,000 students, 26 percent of the total enrollment, attend local private schools. Over the past decade, student enrollment in the SFUSD has been declining by approximately 0.1 percent annually.[954]

SFUSD is the primary public school provider in the City, accommodating approximately 98 percent of the total public school enrollment. Additional public school facilities include court-sponsored facilities (correctional institutions, court ward facilities, etc.) and public charter schools.

[953] Public school attendance based on: California Department of Education, *2008–09 District Enrollment by Grade, San Francisco Unified*, Educational Demographics Unit, DataQuest System, 2009. http://data1.cde.ca.gov/dataquest (accessed online July 6, 2009). The 2005 American Community Survey reported that public school attendance represents approximately 74 percent of the total school attendance in San Francisco, while private school attendance represents 26 percent of the total.

[954] California Department of Education, *DataQuest*, http://data1.cde.ca.gov/dataquest/ (accessed July 2009).

Table III.O-5 Existing Classroom Capacity and Enrollment, SFUSD, 2008

Type of School	*Number of Schools*	*Capacity*	*2008/09 Enrollment*
Elementary Schools	63	29,260	24,939
Middle Schools	13	11,700	11,816
High Schools	16	17,575	19,688
Alternative Schools (varying grade levels)	10	3,900	—
Public Charter Schools (varying grade levels)	2	1,400	—
Total	***104***	***63,835***	***56,443***

SOURCE: San Francisco Unified School District, *San Francisco Unified School District Capital Plan FY 2009–2018*, Appendix; California Department of Education, 2009. Educational Demographics Unit, Data Quest System: 2008–09 District Enrollment by Grade, San Francisco Unified, 2008. http://data1.cde.ca.gov/dataquest (accessed: July 6, 2009).

As shown in Table III.O-5, there is capacity for approximately 63,835 students in existing SFUSD facilities.[955] Table III.O-5 presents an estimate of existing public school enrollment for those schools. Although neighborhoods with a high population of school-age children generate a proportionally high level of demand for nearby schools, SFUSD assigns students to schools based on a lottery system. This system ensures that student enrollment is distributed to facilities that have sufficient capacity to adequately serve the educational needs of students. The SFUSD provides bus transportation to students who attend schools outside of the neighborhood in which they reside.[956]

With enrollment declining in the District, SFUSD has been closing schools. The SFUSD's capital facilities program has focused on replacing older schools and modernizing other facilities. The *San Francisco Unified School District Capital Plan* identifies a range of physical improvements necessary to modernize existing facilities, such as providing access compliant with the Americans with Disabilities Act (ADA), upgrading science and computer labs, expanding arts facilities, and other improvements. In addition, the SFUSD has a backlog of deferred maintenance needs.

Project Vicinity

Schools located in the vicinity of the Project site covering grades K–12 are listed in Table III.O-6 (San Francisco Unified School District Facilities in the Project Vicinity). Schools in the vicinity of the Project site are generally in the Bayview neighborhood, but also include facilities to the north in the Mission neighborhood and to the west in the Visitacion Valley neighborhoods. During the 2008/09 school year, those schools in the Project vicinity had a combined enrollment of 2,980 students and an existing capacity of 5,900 spaces. Public school locations in the Project vicinity are illustrated in Figure III.O-2 (Southeast San Francisco Schools and Libraries).

b. California Department of Education Educational Demographics Unit, 2008–09 District and School Enrollment by Grade, San Francisco Unified School District, 2009.

Under existing conditions, there are approximately 43 school-age children living at the Project site, representing a small percentage of overall SFUSD enrollments. The remaining capacity in the 2008/09 school year to accommodate additional enrollment within the Bayview neighborhood include approximately 1,292 elementary, 1,064 middle school, and 563 high school students (Table III.O-6). As shown in Table III.O-6, schools in the vicinity of the Project site have adequate capacity to serve existing enrollment. The total remaining capacity of those facilities during the 2008/09 school year was approximately 49 percent.

III.O.9 Regulatory Framework

Federal

There are no federal school regulations applicable to the Project.

State

California Senate Bill 50 (SB 50)

The major source of school construction and modernization was the State School Construction Program until the passage of Senate Bill 50 (SB 50) and Proposition 1A, both of which passed on November 3, 1998. SB 50 and Proposition 1A provided a comprehensive school facilities financing and reform program, which authorized a $9.2 billion school facilities bond issue, as well as school construction cost containment provisions

SOUTHEAST SAN FRANCISCO SCHOOLS AND LIBRARIES

and an eight-year suspension of the *Mira*, *Hart*, and *Murrieta* court cases. The provisions of SB 50 prohibit local agencies from denying either legislative or adjudicative land use approvals on the basis that school facilities are inadequate and reinstate the school facility fee cap for legislative actions (e.g., general plan amendments, specific plan adoption, zoning plan amendments), as was allowed under the *Mira*, *Hart*, and *Murrieta* court cases.[957] According to *Government Code* Section 65996, the development fees authorized by SB 50 are deemed to be "full and complete school facilities mitigation." The legislation also recognized the need for the fee to be adjusted periodically to keep pace with inflation. These provisions are in effect and will remain in place as long as subsequent state bonds are approved and available. As a result of this legislation, school districts would continue to levy a school fee under existing rules (*Government Code* Sections 65995, 65995.5, and 65995.7).

Local

SFUSD School Impact Fees

The SFUSD began collecting State-authorized school impact fees in 1987, which are collected to mitigate impacts associated with enrollment growth (e.g., new residential development). The SFUSD collects fees for all construction and building permits issued within the City. Developer fee revenues are used, in conjunction with other SFUSD funds, to support efforts to complete capital improvement projects.[958] Table III.O-7 (San Francisco Unified School District Adopted School Impact Fees) presents the current fees for new construction, by facility type, when building permits are issued.

Table III.O-7 San Francisco Unified School District Adopted School Impact Fees

Development Type	*Fee per Square Foot*
Residential	$2.24
Office	$0.27
Research and Development	$0.24
Hospitals	$0.22
Industrial/Warehouse/Manufacturing	$0.21
Retail and Services	$0.18
Lodging/Hotel/Motel	$0.09

SOURCE: SFUSD, Personal communication SFUSD Real Estate Department, to Chad Mason, PBS&J, July 28, 2009.

[957] There are a series of appellate decisions known as "Mira/Hart/Murrieta." In *Mira Development Corp. v. City of San Diego* (Mira), 205 Cal. App. 3d 1201 (1988); *William S. Hart Union High School District v. Regional Planning Commission* (Hart), 226 Cal. App. 3d 1612 (1991); and *Murrieta Valley Unified School District v. County of Riverside* (Murrieta), 228 Cal. App. 3d 1212 (1991), the courts held that the limitations of the School Facilities Law of 1986 only applied to municipalities when they made adjudicative decisions (such as approvals of parcel maps, use permits, and building permits) but not when they made legislative decisions (such as general plan amendments, zoning changes, and development agreements). III.O.10 Impacts

Significance Criteria

The City and Agency have not formally adopted significance standards for impacts related to school services, but generally consider that implementation of the Project would have significant impacts if it were to:

O.c Result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, [or the] need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios or other performance objectives of the school district

Analytic Method

Impacts on schools are determined by analyzing the estimated increase in student population as a result of Project build-out in 2032 and comparing the increase to the capacity of schools in 2030, the closest year to Project build-out for which housing projections have been calculated, to determine whether new or altered facilities would be required, the construction of which could result in substantial adverse environmental effects.

Additionally, the Project's potential contribution to cumulative school impacts is evaluated.

Construction Impacts

Impact PS-5: School Services during Construction

Impact PS-5 **Construction activities associated with the Project would not affect the provision of school services by decreasing access to school services. (No Impact) *[Criterion O.c]***

Construction of the Project would not result in impacts to the SFUSD system, as construction of the Project would not itself create new residents or students. Also, no SFUSD facilities are located on the Project site. All school services would be available to the community throughout the duration of project construction. As such, no impact to school services during construction of the project would occur. No mitigation is required.

Operational Impacts

Impact PS-6: School Services during Operation

Impact PS-6 **New students associated with implementation of the Project would not require new or expanded school facilities, the construction of which could result in substantial adverse impacts. (Less than Significant) *[Criterion O.c]***

The California Department of Education estimates that one dwelling unit would generate an average of 0.7 students, consisting of 0.5 elementary or middle school students and 0.2 high school students.[959] These

[959] San Francisco, *Eastern Neighborhoods Community Rezoning and Area Plans Final Environmental Impact Report*, August 2008, Initial Study p. 42. This report is on file as part of Case No. 2004.0160E and available for public review at the Planning Department, 1650 Mission Street, Suite 400.

rates are a result of statewide sampling that incorporates widely varying dwelling unit types, households, and other demographic characteristics and are routinely used by school districts that have not developed rates for their local jurisdictions.[960] However, those rates do not reflect demographic characteristics of San Francisco, which has fewer children per household than most communities. Therefore, for planning purposes, the SFUSD uses a student generation rate of 0.203 students (including elementary, middle, and high school students) per new housing unit.[961] The number of students generated by the Project was determined by multiplying the number of Project housing units by the student generation factor of 0.203. The number of students was distributed evenly by grade.

Table III.O-8 (Project Buildout Public School Enrollment Compared to SFUSD Capacity) presents the student enrollment that would be generated as a result of the Project, based on generation rates used by the SFUSD. While 26 percent of the total school-age children in San Francisco now attend private schools,[962] Table III.O-8 conservatively assumes that 100 percent of the school-age children associated with the Project would attend public schools.

Table III.O-8 Project Buildout Public School Enrollment Compared to SFUSD Capacity

Analysis Area	*Elementary School (Grades K–5)*	*Middle School (Grades 6–8)*	*High School (Grades 9–12)*	*Total*
Candlestick Point[a]	735	368	490	1,593
HPS Phase II[b]	248	124	166	538
Total	***983***	***492***	***656***	***2,131***
2030 Citywide Enrollment[c]	33,036	16,518	22,024	71,573
2008 SFUSD Capacity[d]	29,260	11,700	17,575	63,835
2030 Citywide Shortfall	3,776	4,818	4,449	7,738

SOURCE: ABAG Projections 2007; PBS&J, 2009.

The number of new students in the Project site was determined by multiplying the number of proposed housing units by the student generation factor of 0.203. The number of students was distributed evenly by grade.

a. For Candlestick Point, 7,850 residential units multiplied by 0.203 SFUSD student generation rate would result in 1,594 students. 1,594 students divided by 13 grade levels would result in 123 students per grade. 123 students per grade level multiplied by six grade levels for elementary school equals 735; multiplied by three grade levels for middle school equals 368; and by four grade levels for high school equals 490. Totals may not equal due to rounding.

b. For HPS Phase II, 2,650 residential units multiplied by 0.203 SFUSD student generation rate would result in 538 students. 538 students divided by 13 grade levels would result in 41 students per grade. 41 students per grade level multiplied by six grade levels for elementary school equals 248; multiplied by three grade levels for middle school equals 124; and by four grade levels for high school equals 166. Totals may not equal due to rounding.

c. 2030 enrollment was calculated as follows: the 2008/09 SFUSD enrollment was divided by the 2005 Citywide school-age population (5–19 years old), which yields a ratio of 0.558. Similarly, the 2030 Citywide school-age population (5–19 years old) was multiplied by the ratio of 0.558 to yield a projected 2030 SFUSD enrollment of 71,573. Enrollment was distributed evenly across the grade levels. Totals may not equal due to rounding.

d. The total includes capacity for 5,300 students in varying grade levels in alternative schools and public charter schools.

[960] San Francisco, *Eastern Neighborhoods Community Rezoning and Area Plans Final Environmental Impact Report*, August 2008, Initial Study p. 42. This report is on file as part of Case No. 2004.0160E and available for public review at the Planning Department, 1650 Mission Street, Suite 400.

[961] San Francisco, *Eastern Neighborhoods Community Rezoning and Area Plans Final Environmental Impact Report*, August 2008, Initial Study p. 42. This report is on file as part of Case No. 2004.0160E and available for public review at the Planning Department, 1650 Mission Street, Suite 400.

[962] US Census Bureau, American FactFinder, *2005–2007 American Community Survey 3-Year Estimates: County of San Francisco*, 2005. http://factfinder.census.gov (accessed online July 6, 2009).

As shown in Table III.O-8, a total of approximately 2,131 school-age children would live within the Project site following full build-out of the Project. Currently, at Candlestick Point, there are approximately 43 students associated with the Alice Griffith public housing site. After build-out of the Project, there would be approximately 1,593 school-age children living at Candlestick Point. There are currently no students at the HPS Phase II site. After build-out of the Project, there would be approximately 538 total students at the HPS Phase II site.

Comparing the 2008 SFUSD school capacity of 63,835 to a projected 2030 population of 71,573 school age children (recognizing that Project occupancy is projected to occur two years later, in 2032), there is a projected shortfall of about 7,738 seats Citywide, or about a 12 percent shortfall.

As discussed in Section III.O.2 (Setting), improvements are planned for many SFUSD schools, such as replacing older schools and modernizing other facilities. The *San Francisco Unified School District Capital Plan* identifies a range of physical improvements necessary to modernize existing facilities, such as providing access compliant with the *Americans with Disabilities Act* (ADA), upgrading science and computer labs, expanding arts facilities, and other improvements. Those improvements will improve accessibility, add new laboratories, provide better access to computing technology, and provide other advantages over existing facilities. While there are no plans to reduce school capacity at the Project site, in the event that schools located in the Project site reach capacity by the year 2032 (or 2030 as the projections indicate), either due to a reduction in space or an increase in classroom size, the SFUSD may assign students to schools based on a lottery system, which would ensure that student enrollment is distributed to facilities that have sufficient capacity to adequately serve the educational needs of students.

The analysis takes into consideration court decisions that have held that increased enrollment resulting in school overcrowding is considered a "social" rather than a physical environmental impact and is not, in itself, a significant environmental impact requiring mitigation under CEQA (*Goleta Union School District vs. Regents of University of California* [2d Dist. 1995]).[963] Instead, increased school enrollment may only lead to such an impact if the increase would ultimately require physical changes in the environment. Changes such as shifting students to other facilities, beginning year-round schools, and increasing the use of portable classrooms would be considered "social" effects, whereas a condition of present overcrowding and projections of increasing enrollments, which would likely necessitate constructing a new school, changing bus routes, and altering traffic patterns, could be considered "physical" effects. Also, state *Government Code* Sections 65995 and 65996 have pre-empted and limited the ability of cities to exercise their power to mitigate school impacts. The duty of a lead agency to mitigate school impacts beyond State-mandated fees can occur only when a physical environmental effect beyond the mere addition of students to a school occurs. Residential growth within the City over the next 30 years would be addressed by payment of SB 50 fees, and consequently school capacity may have improved by the time Project students are generated. Construction activities associated with proposed public facilities are considered part of the overall Project. A discussion of project-related construction impacts, including those associated with the construction of public facilities, is provided in the applicable sections of this EIR, including Section III.D, Section III.H, Section III.I, Section III.J, Section III.K, and Section III.M. Construction impacts would be temporary. While it is likely that construction of the various public facilities would not result in significant impacts

[963] California Natural Resources Agency, *CEQA Court Cases Decided in 1995*. http://ceres.ca.gov/ceqa/cases/1995/goleta95.html.

(either individually or combined), construction of the entire development program, of which the public facilities are a part, would result in significant and unavoidable impacts related to construction noise and demolition of an historic resource; all other construction-related impacts would be less than significant (in some cases, with implementation of identified mitigation). Refer to Section III.D, Section III.H, Section III.I, Section III.J, Section III.K, and Section III.M for the specific significance conclusions for construction-related effects.[964]

Further, SFUSD could choose to address its potential future shortfalls in capacity through a wide range of options, including shifting students to other facilities, beginning year-round schools, and/or increasing the use of portable classrooms. While schools in the Project vicinity have approximately 49 percent capacity remaining in 2008/09, it is likely that a 12 percent Citywide overcapacity of SFUSD as a result of citywide population growth in 2030 would occur. The school impact fees paid pursuant to SB 50 would go toward maintaining or improving school facilities to accommodate growth in school attendance. Therefore, SB 50 would ensure that future facilities are provided, and this impact is considered less than significant. No mitigation is required.

Cumulative Impacts

The geographic context for the analysis of cumulative impacts associated with schools is the City of San Francisco. The past and present development in the City is described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable future development forecasts are based on projections of future growth and take into account projects going through the entitlement process. The City of San Francisco and the San Francisco Unified School District provide public services within the City's boundaries. SFUSD is the primary public school provider in the City, accommodating approximately 98 percent of the total public school enrollment. Additional public school facilities include court-sponsored facilities (correctional institutions, court ward facilities, etc.) and public charter schools. As shown in Table III.O-4 there is capacity for approximately 63,835 students in existing SFUSD facilities.

Development of cumulative projects within the City would result in increased population and employment-generating uses, which would result in an associated increase in the number of students to be served by the SFUSD. Over the past several years, the student population has declined, and some schools have been closed, and, as noted, the SFUSD is concentrating its efforts on replacing older schools and modernizing other facilities. The SFUSD began collecting State-authorized school impact fees in 1987, which are collected to mitigate impacts associated with enrollment growth (e.g., new residential development). The SFUSD collects these fees for all construction and building permits issued within the City. Developer fee revenues are used, in conjunction with other SFUSD funds, to support efforts to complete capital improvement projects. According to *Government Code* Section 65996, the development fees authorized by SB 50 are deemed to be "full and complete school facilities mitigation." Therefore, cumulative development within the City would not result in a significant schools impact. The Project's cumulative impact would be less than significant.

[964] The impact statements provided in each technical section of the EIR differentiate between construction impacts and operational or development impacts, and all identified mitigation measures are contained in the impact analysis. In addition, Table ES-2 in the Executive Summary of this EIR also summarizes all impact statements, the level of significance before mitigation, any identified mitigation measures, and the level of significance after mitigation.

Libraries

III.O.11 Setting

The San Francisco Public Library (SFPL) operates the Main Library at the Civic Center and 28 neighborhood branches distributed throughout San Francisco, providing information in books, other print and non-print formats, or electronic form. The SFPL is dedicated to providing "free and equal access to information, knowledge, independent learning, and the jobs of reading" for San Francisco.[965] During the 2007/08 fiscal year, the main library's collection was 1,297,853 volumes, and all the branch libraries had a collection of 1,203,126 volumes, for an SFPL total of 2,500,979 volumes.[966] Community-based branch libraries, as well as the Main Library, provide reading rooms, book lending, information services, access to technology, and library-sponsored public programs. Most branches offer an event almost every day, often for pre-school and elementary school children: story time, crafts, and videos. Programs for youth include reading and computer-oriented clubs.

All SFPL branch libraries offer books at adult, teen, and children's reading levels. Basic collections consist of fiction, nonfiction, and reference books; magazines; newspapers; audio books; CDs; and DVDS. If specific materials are not available at an SFPL branch, items may be obtained through the library's request system, Link+, or interlibrary loan. Link+ allows SFPL library patrons to borrow items from participating libraries throughout California. Items typically arrive within four days and may be returned to any SFPL branch.[967] Interlibrary Loan involves loaning items from various libraries and institutions in North America that agree to loan items to one another, which may include local universities, such as University of California Berkeley, San Francisco State University, or Stanford University.[968] Most of SFPL's collection of electronic resources is accessible from all branch locations and online 24 hours a day at the SFPL website.

There are three branch libraries within a 2-mile radius of the Project site: the Bayview/Anna E. Waden Branch, the Portola branch, and the Visitacion Valley branch; which are described in Table III.O–9 (Library Branches Serving the Project Site). Public library locations in the Project vicinity are illustrated in Figure III.O–2. In addition to the standard items available at branches, the Bayview branch offers a collection of materials by and about African Americans and has a medium-sized collection of Chinese language materials and a small collection of Spanish language materials. Both the Portola and Visitacion Valley branches offer a medium-sized collection of Chinese language materials. These materials are available to address the needs of each branch community.

Table III.O-9 Library Branches Serving Project Site

Branch	*Location*	*Distance from Project Site (mile)*	*BLIP Improvements*	*Size of New Collection at Opening*
Bayview	5075 3rd Street	0.5	New Branch. Not Yet Begun.	43,000 to 45,000 volumes.
Portola	380 Bacon Street	1.5	New Branch. Opened February 2009	33,000 volumes
Visitacion Valley	45 Leland Avenue	1.0	New Branch. Reopens 2010	35,000 to 40,000 volumes

SOURCE: San Francisco Public Library Website. Branch Library Improvement Program. http://sfpl.org/news/blip/improvementprogram.htm (accessed September 14, 2009); Written correspondence with Brian Bannon, Chief of Branches, San Francisco Public Library with Allison Wax, PBS&J on September 9, 2009.

All branches have room for 10 to 15 percent growth.

In 1994, San Francisco voters passed Proposition E, a charter amendment that created the Library Preservation Fund. This measure established a dedicated fund to be used to provide library services and materials, as well as to operate library facilities. Proposition E established a 15-year mandate that requires the City to maintain funding for the San Francisco Public Library at a level no lower than what it spent during the 1992 and 1993 fiscal year. Voters renewed the Library Preservation Fund in November 2007 (Proposition D).

Branch Library Improvement Program

The Branch Library Improvement Program (BLIP) was launched as a result of a bond measure passed in November 2000 to provide $106 million in funding to upgrade San Francisco's branch library system, and Proposition D, which passed in November 2007, authorizing additional funding to improve the branches. The BLIP is intended to provide the public with seismically safe, accessible, technologically updated, and code-compliant City-owned branch libraries in every neighborhood[969]. Improvements to be made at each branch were determined through the preparation of a "Community Needs Assessment" for each branch, with public meetings, community surveys, and outreach to neighborhood organizations. Design options, such as public meeting rooms, more computers, separate teen facilities, child and adult reading areas, and other library services, were considered. Choices about each branch reflect its budget (which is fixed) input from staff, and input from the neighborhood, in part through community meetings to discuss services and architectural plans.

The SFPL has implemented a number of interim programs to serve the public while branches are closed for renovation or replacement. These include increasing hours at nearby branches, holding programs at neighborhood schools and community centers, and offering bookmobile services.

One of the priorities of the 2000 bond measure was to replace four branches housed in leased facilities with City-owned branches, two of which are located in the Portola and Visitacion Valley neighborhoods. New Portola and Visitacion Valley branches have since been constructed or are currently being constructed. The new one-story, 6,300-square-foot Portola branch opened in February 2009. The branch opened with a collection of 33,000 items and has room to grow 10 percent to 15 percent. Construction of the new Visitacion Valley branch began in summer 2007 and is scheduled to be completed in 2010. The new branch will be approximately 8,500 square feet and will open with a collection of between 35,000 and 40,000 volumes and has been designed to accommodate an additional 10 percent to 15 percent in collection size.

[969] San Francisco Public Library, *Branch Library Improvement Program—Frequently Asked Questions*, 2009. http://www.sfgov.org/site/frame.asp?u=http://www.sfpl.org/ (accessed: July 8, 2009).

The Bayview/Anna E. Waden branch, one of the branches serving the Bayview neighborhood and the Project site, was also identified for renovation under the BLIP, and has been funded as part of Proposition D. Because of the increased service needs in the area, the community support for a new branch, and the difficulty meeting the service needs with a renovation, the SFPL decided to build a new Bayview branch library. The Bayview branch library will be at the same site as the existing branch and the expansion will occupy an adjacent site. The new branch will be approximately 9,000 square feet and will open with a collection of 43,000 to 50,000 volumes with room to grow its collection by 10 to 15 percent. Construction is scheduled to begin in early 2010 and open in late 2011. During construction, library services will be provided by holding programs at neighborhood schools and community centers and by a bookmobile service.[970]

III.O.12 Regulatory Framework

Federal

There are no federal library service regulations applicable to the Project.

State

There are no state library service regulations applicable to the Project.

Local

San Francisco Public Library Strategic Plan (2003–2006)

The SFPL Strategic Plan was adopted in 2003 and remains the guiding document for the SFPL. As stated in the SFPL Strategic Plan, there is no national standard for library service. Instead, each library must evaluate how it may best meet the needs of the community. To this end, the SFPL has developed the Strategic Plan that provides every library facility and program with a unifying organizational vision and system-wide goals. These goals are broad and flexible to tailor services to each unique neighborhood. The Strategic Plan also provides a framework to consider opportunities for new programs and services.[971]

III.O.13 Impacts

Significance Criteria

The City and Agency have not formally adopted significance standards for impacts related to library services, but generally consider that implementation of the Project would have significant impacts if it were to:

O.d Result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, [or the] need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios or other performance objectives for library services

[970] San Francisco Public Library, *New Bayview/Anna E. Waden Branch Library Frequently Asked Questions*, 2009. http://www.sfgov.org/site/frame.asp?u=http://www.sfpl.org/ (accessed: July 8, 2009).
[971] San Francisco Public Library Strategic Plan 2003–2006.

Analytic Method

Impacts on library services are considered significant if an increase in population or development levels would result in an increased demand for library services that would require the need for new or physically altered library facilities in order to maintain acceptable service ratios, the construction of which could result in substantial adverse environmental effects.

Additionally, the Project's potential contribution to cumulative library impacts is evaluated.

Construction Impacts

Impact PS-7: Library Services during Construction

Impact PS-7 **Construction activities associated with the Project would not affect provision of school services by decreasing access to library services. (No Impact) *[Criterion O.d]***

Construction of the Project would not result in impacts to the San Francisco Public Library system, as the construction itself would not result in an increase in population requiring library services. Also, no library branches are located on the Project site. All library services would be available to the community throughout the duration of project construction. As such, no impact to library services during construction of the project would occur. No mitigation is required.

Operational Impacts

Impact PS-8: Library Services during Operation

Impact PS-8 **Implementation of the Project would not result in an increase in demand for library services that is not met by existing library facilities in the vicinity that have been expanded or updated. (Less than Significant) *[Criterion O.d]***

Residential and nonresidential development associated with the Project would increase demand for local library services in the Bayview neighborhood. The Project would result in a population increase of 24,465 residents and 10,730 employees. The development at Candlestick Point would result in a population increase of 18,290 residents and 3,476 employees, and the development at HPS Phase II would result in a population increase of 6,175 residents and 7,254 employees. Although the Project would result in a substantial direct and indirect population increase within the Bayview neighborhood, library branches serving the Project site, including the new Portola branch (opened in 2009), the Visitacion Valley branch currently under construction (opening in 2010), and the Bayview branch to be expanded beginning in 2010 (opening in late 2011), would continue to meet the demands of the community. Each of the three new library branches serving the Project are designed to accommodate 10 to 15 percent growth in their collection size.

Services offered at each library are based on a variety of factors including collection size, and by weighing the benefits of adding community rooms, study areas, and designated spaces for teens, children, and adults. All of the library branches serving the Project site were designed to accommodate 10 to 15 percent growth

in its collection size.[972] If materials are not available at a specific branch, materials can be made available in a matter of days through the SFPL's delivery system, which provides for the delivery of materials from one branch to another branch, utilizes Link+ system to access books at participating libraries in California, or request a loan from the Interlibrary Loan system, which involves loaning items from various libraries and institutions in North America. As such, materials available to library patrons are not limited to those housed at their neighborhood library, making the number of volumes at each branch location not a valid measure to evaluate library services. In the event that additional services are needed in any neighborhood, the SFPL dispatches a bookmobile to address immediate needs and the SFPL's current Strategic Plan would provide guidance as to how to address increased demands resulting from population growth in consideration of the branch's fixed budget.

The new SFPL branches, which would all be completed upon build-out of the Project, would accommodate increased demand from the Project. No additional library facilities would be required to accommodate development proposed in the Project. Impacts to libraries would be less than significant, and no mitigation is required.

However, space within the Project site would also be dedicated to the provision of library services to supplement the expanded Bayview branch library. As part of the Project, a 1,500 gsf reading room and space for automated book-lending machines would be integrated into the community retail and public facilities uses that are proposed.

Cumulative Impacts

The geographic context for the analysis of cumulative impacts associated with libraries is the City of San Francisco. The past and present development in the City is described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable future development forecasts are based on projections of future growth and take into account projects going through the entitlement process. The City of San Francisco provides public services within the City's boundaries.

The Branch Library Improvement Program (BLIP), launched as a result of a 2000 bond measure, included plans for construction of eight new library branches. The BLIP includes completion of a "Community Needs Assessment" for each branch, with public meetings, community surveys, and outreach to neighborhood organizations. Most branch libraries in the City are currently being renovated, or are planned for future renovation, under the BLIP program. As stated in the SFPL Strategic Plan, there is no national standard for library service and each library must evaluate how it may best meet the needs of the community. To this end, the SFPL has developed the Strategic Plan, which provides every library facility and program with a unifying organizational vision and systemwide goals.

Development of reasonably foreseeable future projects within the City, in conjunction with past and present development, would increase resident population as well as generate new employment, which could increase demand on public library resources. The SFPL Strategic Plan is based, in part, on population projections for build-out of the General Plan, which includes the development anticipated at the Project site. All cumulative projects (past, present, and reasonably foreseeable) that are within the identified

[972] Written correspondence with Brian Bannon, Chief of Branches, San Francisco Public Library with Allison Wax, PBS&J, September 9, 2009.

population projections would be understood to have been considered during development of the Strategic Plan. Therefore, it is not anticipated that cumulative development would result in a significant cumulative impact to library services.

Residential and non-residential development associated with the Project would increase demand for local library services in the Bayview neighborhood. As noted, the existing SFPL branches and construction of the proposed Reading Room that is part of HPS Phase II would accommodate the increased demand from the Project. No additional library facilities would be required to accommodate development proposed in the Project. Therefore, no new or physically altered library facilities would be required in order to maintain acceptable service ratios for public library services. There is no significant cumulative impact with respect to library resources, and the Project's cumulative impact would be less than significant.

[This page is intentionally left blank.]

SECTION III.P RECREATION

III.P.1 Introduction

This section of the EIR analyzes whether the Project would (1) increase the use of existing parks and recreational facilities such that substantial physical deterioration or degradation of the facilities would occur or be accelerated or that new or expanded facilities would be required; (2) result in substantial adverse construction-related effects associated with the provision of new or physically altered parks and recreational facilities, whether on site or off site; and/or (3) adversely affect existing recreational facilities. This section analyzes the potential for both Project level and cumulative environmental impacts. The analysis in this section concludes that the Project could have potentially significant environmental impacts related to the timing of proposed park; therefore, a mitigation measure is included.

Data used in this section includes information obtained from the San Francisco Recreation and Park Department (SFRPD), the California Department of Parks and Recreation (CDPR), as well as the California Department of Parks and Recreation *Candlestick Point State Recreation Area General Plan* (CPSRA General Plan), Association of Bay Area Governments (ABAG) *San Francisco Bay Trail Plan*, ESA *Windsurfing Memorandum* (refer to Appendix P1 [Windsurfing Report]), San Francisco Bay Conservation and Development Commission *San Francisco Bay Plan*, San Francisco Bay Conservation and Development Commission *Bay Area Water Trail Plan*, and the *City of San Francisco General Plan*.

III.P.2 Setting

Existing Parks and Recreational Facilities

For purposes of this analysis, parks are generally defined as areas of land set aside for various recreational opportunities for the public. Recreational facilities are those structures and/or improvements that are built at parks (e.g., benches, picnic tables, tennis courts, etc.). Open space areas are typically unimproved parkland. Therefore, parks and recreational facilities are typically used interchangeably, whereas open space areas refer to those areas where the land is either kept in its natural state or enhanced in order to return the land to its natural state. However, when calculating the City's overall park acreage, open space areas are considered part of the overall total.

Citywide and Regional Resources

Property in San Francisco that is permanently dedicated to publicly-accessible park and recreational uses totals approximately 5,886 acres.[973] The population of San Francisco as of January 1, 2008, was 824,525,[974] yielding a ratio of, or 7.1 acres per 1,000 San Francisco residents. The City has not established a citywide target ratio of parkland to residents, nor has it adopted a *Quimby Act* ordinance requiring land dedications

[973] San Francisco Planning Department, personal communication, Sue Exline, October 26, 2009.
[974] California Department of Finance, E-1 Population Estimates for Cities, Counties, and the State with Annual Percent Change—January 1, 2008 and 2009 http://www.dof.ca.gov/research/demographic/reports/estimates/e-1_2006-07(accessed online June 12, 2009), and Section III.,C (Population, Employment, and Housing).

or in-lieu fees, because San Francisco's population density, small land mass, and other development constraints make such policies infeasible.[975]

The SFRPD maintains more than 200 parks, playgrounds, and open spaces throughout the City, as well as 15 recreation centers, nine swimming pools, five golf courses, and a number of tennis courts, ball diamonds, athletic fields, and basketball courts. The SFRPD also manages the Marina Yacht Harbor, Candlestick Park stadium, and the Lake Merced Complex. The CDPR owns approximately 120.2 acres at Candlestick Point State Recreation Area (CPSRA) within the Project site, as stated in Table II-4 (Candlestick Point Proposed Land Use Summary) in Chapter II (Project Description). (This acreage does not include the Yosemite Slough Restoration area, which is approximately 34 acres.) The San Francisco Bay Trail (Bay Trail) is a multipurpose recreational trail that, when complete, will encircle San Francisco and San Pablo Bays with a continuous 400-mile network of bicycling and hiking trails. It will connect the shoreline of all nine Bay Area counties, link 47 cities, and cross the major bridges in the region. To date, approximately 290 miles of the alignment have been completed.[976]

In the vicinity of the Project site, a segment of the Bay Trail runs from Heron's Head Park around the India Basin Shoreline, with a gap in the middle of the segment near the north side of HPS. In addition, a segment of the trail runs from Candlestick Park south to the southern boundary of Candlestick Point.

As shown in Figure III.P-1 (Existing and Approved Parks and Open Space) there are numerous existing public parks and open spaces located within the Project site and in the nearby vicinity.

Resources on the Project Site

Two existing parks and recreational facilities, encompassing approximately 203 acres, are located within the Candlestick Point site, as illustrated by Figure III.P-1. These existing parks include the CPSRA and Candlestick Park (home of the existing 49ers stadium). There are no existing public open space areas at the HPS Phase II site.

CPSRA

CPSRA (120.2 acres), on the shoreline of Candlestick Point, was acquired by the State in 1977 for development as a State recreation area. The southern portion of the park is the most developed and actively used area (totaling approximately 47 acres), while the northern areas are unimproved and underutilized (totaling approximately 73 acres). The CPSRA lands to the northeast of Yosemite Slough include a now defunct auto salvage yard, old warehouse, and two business locations that are currently occupied by a sound studio and a cabinet shop. CDPR leases the buildings to these tenants on a month-to-month basis. The southern portions of the CPSRA include picnic areas, a fitness course for seniors, a bike path, shoreline access to the Bay for water-dependent recreation, and recreational trails (Photo 1). CPSRA land to the north and east of the Candlestick Park stadium is currently used for stadium parking; this area total approximately 40 acres. Other portions of the CPSRA site contain construction rubble and debris, such as

[975] City of San Francisco General Plan, Recreation and Open Space Element, 1986.

Candlestick Point — Hunters Point Shipyard Phase II EIR

EXISTING AND APPROVED PARKS AND OPEN SPACE

FIGURE III.P-1

the Last Rubble Pile Disposal Site (Photo 2). Until recently, the Last Rubble area was characterized by large piles of rubble and debris, remnants of the site's previous use as a dumping ground. California State Parks, with a grant from the California Integrated Waste Management Board, removed 10 acres of rubble and debris in 2009. As a result of this, the majority of the rubble and debris was either removed or crushed on site. Yosemite Slough is part of the CPSRA, but is not within the Project site except for at its neck, where the proposed bridge would be constructed.

The annual visitation for day use at CPSRA for 2007/2008 was reported as 15,200 paid day-use passes and 200,283 free day-use visitors, for a total of 215,483.[977]

Candlestick Park

Candlestick Park (83 acres),[978] is the site of the stadium owned by the SFRPD and leased by the San Francisco 49ers National Football League team. The existing stadium, built in 1960, seats 70,000 and is used for football games and other non-football entertainment events.

Candlestick Point State Recreation Area is comprised of improved and unimproved park areas.

Improved Area. *Photo 1 is of Main Beach, an already improved area of the CPSRA which includes multi-purpose trails, habitat areas, vegetation, and access to the waterfront. This area is located in the proposed Wind Meadow and Heart of the Park areas (discussed in detail under Impact RE-2).*

Unimproved Area. *Photo 2 is of the Last Rubble Pile Disposal Site. This area, located within the northeastern area of the CPSRA, was formerly used as a concrete dumping ground. More recently, this area underwent debris removal and was marginally improved as a result of a grant from the Integrated Waste Management Board in 2009.*

Other Nearby Facilities. As illustrated by Figure III.P-1, the following SFRPD facilities are within one-quarter mile of the Project site, considered to be walking distance for many users:

- Gilman Park (4.6 acres) is a playground located immediately northwest of Candlestick Park. It includes plastic and metal play equipment with restrooms, picnic tables, a dog area, and a basketball court.

[977] California State Park System, *Statistical Report, 2007/2008 Fiscal Year.* http://www.parks.ca.gov/pages/795/files/07-08%20statistical%20report%20final%20online%20version_2.pdf (accessed on October 13, 2009).
[978] The stadium itself occupies 14.5 acres. The rest of the site is devoted to ancillary uses, such as parking.

- Bayview Park (44 acres), which is off Third Street and Key Avenue immediately west of the Project site, includes picnic areas, natural habitat areas, and recreational trails.
- India Basin Shoreline Park (11.8 acres), on the India Basin Shoreline north of Innes Avenue, includes two children's playgrounds, picnic areas, shoreline access to the Bay for water-dependent recreation, and recreational trails.
- India Basin Flats (also called India Basin Open Space) is unimproved SFRPD property on the Bay periphery of India Basin, northwest of the Project site, off of Innes Avenue. India Basin Flats consists of about 4.5 acres[979] of public land (also referred to as "India Basin Open Space", as indicated on Figure III.P-1, as well as additional, adjacent acreage that is privately held (and not indicated on Figure III.P-1).
- Milton Myer Recreation Center at Kiska Road is a multipurpose facility with meeting spaces, an indoor gymnasium, outdoor game courts, and a children's playground.
- New parks and open spaces (approximately 36 acres) are under development at the HPS Phase I site, adjacent to HPS Phase II.[980] Those parks would provide passive open space, gathering areas, tot lots, trails, view terraces, and picnic facilities.

Other facilities (most of which are operated by the SFPRD) that are located beyond a quarter mile of the Project site, but within approximately one-half-mile of the Project site, include the following:

- LeConte Avenue Mini Park (0.5 acre) is adjacent to and west of Bayview Park (just west of the area shown on Figure III.P-1).
- Bayview Playground (4.6 acres) is a children's playground on Third Street between Armstrong and Carroll Streets that also contains a pool and a softball field.
- The Bayview Hunters Point Multipurpose Senior Center, at Yosemite Avenue and Third Street, offers a range of services and activities for seniors. The Senior Center is not operated by the SFPRD.
- Heron's Head Park (24 acres), formerly known as Pier 98, is a restored wetland owned by the Port of San Francisco and used for research, education, afterschool activities, and natural habitat.
- Other nearby parks also include Hill Top Park (3.4 acres), which includes grassy areas and walking paths; Adam Rogers Park (2.8 acres), which is just south of Hill Top Park, and contains a basketball court, a children's playground, a restroom, and a community garden; and Shoreview Park (0.5 acre), just east of Hill Top Park and on the opposite side of the Jedediah Smith School, contains a children's playground and an open grassy area. Shoreview Park is not operated by the SFPRD.

A number of other small neighborhood parks, playgrounds, and recreational facilities are located beyond a half-mile of the Project site, but within zip code 94124 (east of I-280 and US-101). These include Ridgetop Plaza (0.3 acre), Youngblood-Coleman Playground (6.1 acres), the Joseph Lee Recreation Center (1.9 acres), the Palou-Phelps Mini-Park (3.6 acres), and the Silver Terrace Playground (5.5 acres). While these uses are more than one-half mile from the Project site, they are accessible via direct street connections and are not separated from the Project site by freeways or other physical barriers. Significant other regional recreational resources and parks in the City include Golden Gate Park, Crissy Field, Lake Merced Park, McLaren Park and the Presidio.

[979] San Francisco Planning Department, Draft India Basin Shoreline Subarea Plan, June 2009.

[980] San Francisco Redevelopment Agency, *Phase I Disposition Development Agreement*, Exhibit D (Public Open Space), 2001. http://www.sfgov.org/site/sfra_page.asp?id=5588 (accessed August 3, 2009). This parkland is expected to be available for use in 2012.

Existing Users

People living and working in a specified area generate local demand for parks and recreational facilities. The current population at Candlestick Point is about 1,113 persons (refer to Table III.C-1 [Existing Population (2005)] in Section III.C [Population, Housing, and Employment]). As stated above, there are a total of approximately 203 acres of existing parks (including the 83-acre stadium site) at the Project site. The local population, however, does not have access to the stadium for general park and recreational use. Therefore, based on a park estimate of 120.2 acres (203 acres less the 83-acre stadium), the existing ratio of persons to acres of parkland is 108 acres per 1,000 residents, which is very high because the site is primarily non-residential and includes the large CPSRA.[981]

III.P.3 Regulatory Framework

Federal

Land and Water Conservation Fund Act of 1965

The *Land and Water Conservation Fund Act of 1965* (LWCFA) was enacted to assist in preserving, developing and assuring accessibility to outdoor recreation resources and to strengthen the health and vitality of US citizens. The LWCFA accomplishes these goals by providing funds and authorizing assistance to states in planning, acquiring, and developing land and water areas and facilities, including through the Land and Water Conservation Fund.

Land that has been acquired or developed with the assistance of the federally created Land and Water Conservation Fund cannot be converted to uses other than public outdoor recreation without meeting certain requirements. Any such conversion requires approval by the Secretary of the Interior to ensure that substitute recreation lands of at least equal fair market value and reasonably equivalent usefulness and location are provided. The California Park and Recreation Commission (CPRC) received three LWCFA grants between 1979 and 1981 to assist with the development of trails, picnic areas, and other amenities on approximately 35 acres of the CPSRA. The reconfiguration of the CPSRA, discussed further below, would comply with the LWCFA. Compliance would require the determination of the fair market value of any of these lands that the Project converts to uses other than public outdoor recreation and the provision of replacement lands of at least equal fair market value and reasonably equivalent usefulness and location.

State

Candlestick Point State Recreation Area General Plan

Refer to Section III.B regarding a description of the CPSRA General Plan and its application to the Project. The following information about the CPSRA General Plan is related to the Recreation analysis.

[981] This park-to-population ratio assumes a population of 1,113, as identified in Table III.C-1 (Existing Population [2005]) in Section III.C (Population, Housing, and Employment). The population of 1,113 correlates to the total number of households in the Traffic Analysis Zone, which includes more than the 256 households located in the Candlestick portion of the Project site (e.g., 292). It is likely, therefore, that the population within the Candlestick portion of the Project site is less than 1,113, which would only increase the existing park-to-population ratio.

Conceptual land uses and facilities are shown on the CPSRA General Plan Land Use and Facilities map. The Facilities Element lists the following types of recreational uses for the park: trails (hiking, jogging, and bicycling), group picnic areas, family picnic areas, group campgrounds, fishing piers, wind surfing facilities, a sand beach, a quiet area in the southeastern point, scenic overlooks, and a cultural program center. Maritime facilities include a non-powered boat/wind surfing rental facility; a boating center for boat classes and education; a boat access facility that includes a four-lane launching ramp; a 200-space parking area for car-boat trailers; a boat service station; and a ferry landing. A family dinner restaurant and family picnic rest stop are proposed for the Last Port area to the west of Hermit's Cove, off Harney Way.

Current uses in the park include hiking, limited bicycling, day use picnicking, group picnicking, jogging, nature viewing, three sand beaches, undeveloped windsurfing, two piers used daily by fishermen, and three restroom buildings. The park also includes a park staff/maintenance facility, 140 parking spaces for the developed portion of the park, and a community garden.

Some uses have been identified within the CPSRA as potential uses, although they have not been implemented to date, including: group campgrounds; non-powered boat/wind surfing rental facility; boating center; boat access facility that includes a four-lane launching ramp; ferry landing; boat service center; family restaurant and family group rest stop at Harney Way. There is a boat trailer parking area; however, it is not used for boating activities. Every use that has not been developed is still considered a proposed use under the CPSRA General Plan.[982] As such, the CPSRA General Plan has not been fully realized.

As part of the current General Plan process, CDPR's planning staff will facilitate a public planning process to solicit comments and feedback on any new improvements intended for the park. As such, current design and planning elements described in this document represent a proposal. The proposed vision for the park will undergo further review and is subject to change as a result of the General Plan process.

San Francisco Bay Trail Plan

Refer to Section III.B regarding a description of the San Francisco Bay Trail Plan and its application to the Project. The following information about the San Francisco Bay Trail Plan is related to the Recreation analysis.

The Project would include the construction of the Bay Trail throughout the Project. It would support the proposed waterfront trail connection route identified within a 2005 Gap Analysis Study prepared by ABAG for the entire Bay Trail area for the purpose of identifying gaps in the Bay Trail, as well as strategies to complete the Bay Trail system. Following implementation of the Project, the existing trail south of the Project would ultimately connect to the existing northern trail along the India Basin shoreline. The Bay Trail would be accessible for pedestrians and bicyclists with connections to the existing and new parks, from the western boundary of Candlestick Point near the Harney Way/US-101 interchange, through the CPSRA, Yosemite Slough, and HPS Phase II shoreline to India Basin.

Relevant recreation and trail policies from the Bay Trail Plan that apply to the Project with respect to trail alignment and trail design are listed below:

[982] California Department of Parks & Recreation, 2009. Email communication with Steve Bachman, Senior Park & Recreation Specialist, September 16.

- **Trail Alignment Policies**
  - > Ensure a feasible, continuous trail around the Bay.
  - > Minimize impacts on and conflicts with sensitive environments.
  - > Locate trail, where feasible, close to the shoreline.
  - > Provide a wide variety of views along the Bay and recognize exceptional landscapes.
  - > Investigate water trails as an enhancement to the trail system where necessary or appropriate.
  - > In selecting a route for the trail, incorporate local agency alignments where shoreline trail routes have been approved. Incorporate San Francisco Bay Conservation and Development Commission public access trails where they have been required.
  - > Where existing trails through wetlands are well-maintained and well-managed, the Bay Trail can feasibly be routed there. In these cases, trails should be used according to current regulations. Alternate routes should be provided where necessary and additional buffering/transition areas designed to protect wetland habitats should be provided where appropriate to protect wildlife.
  - > In selecting a trail alignment, use existing stream, creek, slough and river crossings where they are available. This may require bridge widening in some locations. In selecting trail alignments, new stream, creek and slough crossings should be discouraged. Where necessary because acceptable alternatives do not exist, bridging may be considered.
  - > In order to minimize the use of existing staging areas along the shoreline and to reduce the need for additional staging areas, the choice of trail alignment should take full advantage of available transit, including rail service (e.g., Caltrain, BART), ferries, and bus service.
- **Trail Design Policies**
  - > Creation of a regionwide hiking and bicycling trail system can be achieved if planning for all trail facilities takes full advantage of opportunities for connections to other existing and proposed recreational systems. The proposed Bay Trail connector trails, in particular, begin to create a regional network by programming links with the Bay Area Ridge Trail.
  - > Wherever possible, new trails should be physically separated from streets and roadways to ensure the safety of trail users.
  - > Create a trail that is as wide as necessary to accommodate safely the intended use, with separate alignments, where feasible, to provide alternative experiences.
  - > Highlight the interpretive potential of certain trail segments, including opportunities for interpretation, education, rest and view enjoyment.
  - > Incorporate necessary support facilities, using existing parks, parking lots, and other staging areas wherever possible.
  - > Design new segments of trail to meet the highest practical standards and regulations, depending on the nature and intensity of anticipated use, terrain, existing regulations, and standards on existing portions of the trail.
  - > Minimum and maximum standards by use, width, surface, etc. should be developed, to ensure safe enjoyment of the trail and compatibility with surroundings and existing facilities, and to encourage use and design of surfaces for which long-term maintenance will be cost-effective.
  - > Design and route the trail to discourage use of undesignated trails.

> A consistent signing program should be established throughout the trail system, using a Bay Trail logo which will identify trails within the Bay Trail system as distinct from other connecting trails. The choice of materials used should be the concern of the individual implementing jurisdictions and agencies.

> The Bay Trail signing program may include necessary cautionary and regulatory signing, including warnings of seasonal trail closings and other restrictions on trail use. Interpretive signing may be provided to help educate trail users about the surrounding environment and the importance of observing trail use restrictions and staying on designated trails.

> The trailhead signing program may include a variety of information which will enhance the Bay Trail experience. This may include a description of the length and relative difficulty of the trail as a guide for trail users with mobility limitations, available support facilities, available access to other connecting trails, and a description of the habitat resource which emphasizes interpretive information as well as the need to observe posted trail use restrictions.

San Francisco Bay Plan

Refer to Section III.B regarding a description of the San Francisco Bay Plan and its application to the Project. The following information about the San Francisco Bay Plan is related to the Recreation analysis.

Recreation-related objectives and policies of the Bay Plan are contained in Part IV—Development of the Bay and Shoreline: Findings and Policies: Recreation objectives and policies that are relevant to the Recreation analysis emphasize the creation of diverse and accessible water-oriented recreational facilities, such as marinas, launch ramps, beaches, and fishing piers. Such facilities should be provided to meet the needs of a growing and diversifying population, and should be well distributed around the Bay and improved to accommodate a broad range of water-oriented recreational activities for people of all races, cultures, ages, and income levels. Recreational facilities, such as waterfront parks, trails, marinas, live-aboard boats, non-motorized small boat access, fishing piers, launching lanes, and beaches, should be encouraged and allowed by the Commission, provided they are located, improved and managed consistent with BCDC policies. Waterfront parks should emphasize hiking, bicycling, riding trails, picnic facilities, swimming, environmental, historical and cultural education and interpretation, viewpoints, beaches, and fishing facilities.

San Francisco General Plan

The Recreation and Open Space Element of the *San Francisco General Plan* contains several policies pertaining to the development of parks and recreational facilities. The following policies are relevant to the development proposed under the Project:

Objective 1 Preserve large areas of open space sufficient to meet the long-range needs of the Bay region.

Policy 1.1 Protect the natural character of regional open spaces and place high priority on acquiring open spaces noted for unique natural qualities.

Objective 2 Develop and maintain a diversified and balanced citywide system of high-quality open space.

Policy 2.1 Provide an adequate total quantity and equitable distribution of public open spaces throughout the City.

	Policy 2.2	Preserve existing public open space.
	Policy 2.7	Acquire additional open space for public use.
	Policy 2.8	Develop a recreational trail system that links city parks and public open space, ridgelines and hilltops, the Bay and ocean, and neighborhoods, and ties into the regional hiking trail system.
Objective 3	Provide continuous public open space along the shoreline unless public access clearly conflicts with maritime uses of other uses requiring a waterfront location.	
	Policy 3.1	Assure that new development adjacent to the shoreline capitalizes on its unique waterfront location, considers shoreline land use provisions, improves visual and physical access to the water, and conforms to urban design policies.
	Policy 3.2	Maintain and improve the quality of existing shoreline open space.
	Policy 3.3	Create the Bay and Coastal Trails around the perimeter of the City which links open space along the shoreline and provides for maximum waterfront access.
	Policy 3.5	Provide new public open spaces along the shoreline.
Objective 4	Provide opportunities for recreation and the enjoyment of open space in every San Francisco neighborhood.	
	Policy 4.3	Renovate and renew the City's parks and recreation facilities.
	Policy 4.4	Acquire and develop new public open space in existing residential neighborhoods, giving priority to areas which are most deficient in open space.
	Policy 4.6	Assure the provision of adequate public open space to serve new residential development.
	Policy 4.7	Provide open space to serve neighborhood commercial districts.

III.P.4 Impacts

Significance Criteria

The City and Agency have not formally adopted significance standards for impacts related to recreation, but generally consider that implementation of the Project would have significant impacts if it were to:

P.a Increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration or degradation of the facilities would occur or be accelerated

P.b Result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered park or recreational facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, or other performance objectives[983]

[983] Thresholds P.a and P.b are discussed together.

P.c Include recreational facilities or require the construction or expansion of recreational facilities, which might have an adverse physical effect on the environment

P.d Adversely affect existing recreational opportunities

Analytic Method

The Project would provide a wide variety of new and improved parks and open space areas. The Project also proposes an agreement between the CDPR and the City or the Agency to reconfigure the boundaries of CPSRA, which would also result in improvements to the CPSRA. The potential impacts of the proposed agreement are analyzed in Impact RE-3.

The analysis below considers the increase in use that would be generated by the Project and the ability of existing facilities (many of which will be improved by the Project) and new open space that would be provided by the Project to meet that demand. The analysis considers whether an increase in use would result in the substantial physical deterioration of existing recreational facilities (e.g., disturbance of vegetation, accelerated wear on sports facilities and fields, erosion along trails, and an increased potential for increased graffiti and litter) or in the need for new or expanded facilities. The analysis further considers whether the Project would diminish or otherwise adversely affect recreational opportunities at the existing facilities (chiefly CPSRA) on the Project site. The analysis of construction impacts associated with the development of proposed new parks and recreational facilities, which are considered as part of the overall Project, draws on conclusions in other sections of this EIR.

The analysis uses a parkland-to-population ratio to measure demand for recreational facilities. If demand is excessive, then use could result in or accelerate substantial physical deterioration of facilities, or could require the construction of further facilities. If, on the other hand, demand is within an acceptable range, then use will not lead to such impacts. The City does not have an adopted parkland-to-population ratio standard. In the past, the National Parks and Recreation Association has recommended a parkland-to-population ratio as high as 10 acres per 1,000 population. As noted in the Recreation and Open Space Element of the City General Plan, however, "[g]iven the City's existing development patterns, high population density, and small land mass (28,918 acres), [this] standard will not be possible to achieve within the City limits." The General Plan goes on to state that "to the extent it reasonably can, the City should increase the per capita supply of public open space within the City" from the parkland-population ratio at the time of the General Plan's adoption (1986), 5.5 acres per 1,000 residents. This analysis will, therefore, use the 5.5 ratio as a benchmark: a ratio of 5.5 acres of parkland per 1,000 population is sufficient to meet demand for recreational facilities without causing or accelerating substantial physical deterioration of facilities or requiring the construction of further facilities.

This standard is consistent with, and in fact provides for more parkland than, other commonly used standards. For example, the state's *Quimby Act* allows jurisdictions to select a standard from 3 to 5 acres of parkland per 1,000 residents when imposing a parkland mitigation requirement. Other nearby Bay Area jurisdictions (e.g., the City of Palo Alto and the City of Menlo Park) use a standard of 5 acres per 1,000 residents.

The Project's potential contribution to cumulative park and recreation impacts, if any, are also evaluated in the context of existing, proposed, and reasonably foreseeable future development expected in the City.

Construction Impacts

Impact RE-1: Construction of Parks, Recreational Uses, and Open Space

Impact RE-1 **Construction of the parks, recreational uses, and open space proposed by the Project would not result in substantial adverse physical environmental impacts beyond those analyzed and disclosed in this EIR. (Refer to Sections III.D [Transportation and Circulation], III.H [Air Quality], III.I [Noise], III.J [Cultural Resources and Paleontological Resources], III.K [Hazards and Hazardous Materials], and III.M [Hydrology and Water Quality]) *[Criterion P.c]***

The Project includes the construction and improvement of substantial new parks, recreational facilities, and open space. At build-out, the Project would include approximately 336 acres of parks and open space as described in Table III.P-1 (Proposed Parks and Open Space) and illustrated by Figure III.P-2 (Proposed Park and Open Space). Candlestick Point would include approximately 104.8 acres of parks and open space, including the CPSRA; HPS Phase II would include approximately 231.6 acres of parks and open space.

Development of the parks and recreational facilities would require construction activities, which could vary depending the location and type of work. If existing structures are located on identified park sites, such structures could require demolition. Sites would be cleared and graded and construction of these new parks could include installation of utilities (electrical, water, sanitary sewer, and storm drainage); hardscape (e.g., concrete, asphalt, stone, walls, sport-court and play area surfacing, decking/boardwalks); new or renovated site structures (e.g., restrooms, picnic/shade shelter's, kiosks, pavilions, overlooks, piers); and site furnishings (e.g., benches, picnic tables, drinking fountains, play equipment, fencing, artwork, lighting). The installation of shoreline protection features would also occur, where necessary. Site planting would include installation of irrigation systems and would focus on re-vegetation and restoration of native plant communities, where possible, and may include creation of new saltwater and freshwater habitats. Open space areas would generally not require extensive construction activities, but could require re-vegetation, the creation of trails, and other non-invasive activities.

Construction activities associated with the proposed parks and recreational facilities are considered part of the overall Project. A discussion of project-related construction impacts, including those associated with the construction of parks and recreational facilities, is provided in the applicable sections of this EIR, including Section III.D (Transportation and Circulation), Section III.H (Air Quality), Section III.I (Noise), Section III.J (Cultural Resources and Paleontological Resources), Section III.K (Hazards and Hazardous Materials), Section III.M (Hydrology and Water Quality), and Section III.N (Biological Resources). Construction impacts would be temporary. While it is likely that construction of the various park and recreational facilities identified in Table III.P-1 would not result in significant impacts (either individually or combined), construction of the entire development program, of which the parks and recreational facilities are a part, would result in significant and unavoidable impacts related to construction noise and demolition of an historic resource; all other construction-related impacts would be less than significant (in some cases, with implementation of identified mitigation). Refer to Section III.D, Section III.H,

Candlestick Point — Hunters Point Shipyard Phase II EIR

PROPOSED PARKS AND OPEN SPACE

FIGURE III.P-2

Section III.I, Section III.J, Section III.K, and Section III.M for the specific significance conclusions for construction-related effects.[984]

In addition, and as further discussed in Impact RE-2 and the cumulative impact analysis, the Project would provide adequate parks, recreational facilities, and open space to accommodate the expected increase in demand resulting from the Project and cumulative development. No further construction would be required beyond that proposed by the Project.

Operational Impacts

Impact RE-2: Deterioration or Degradation of Existing Parks and Recreational Facilities

Impact RE-2 **Implementation of the Project would not increase the use of existing parks and recreational facilities that would cause the substantial physical deterioration of the facilities to occur or to be accelerated, nor would it result in the need for, new or physically altered park or recreational facilities. (Less than Significant with Mitigation) *[Criterion P.a]***

The Project would bring new residents to the Project site and increase the use of existing parks and recreational facilities, but it would also provide substantial new parks and recreational facilities, improve existing facilities, and provide long-term funding for operation and maintenance.

At build-out of the Project, the projected population within the Project site would increase from approximately 1,113 to approximately 24,465 residents, and employment would increase from 529 to approximately 10,730 jobs (refer to Section III.C of this EIR). The increase in population and employment would likely result in an increase in the use of existing parks, recreational facilities, and open space. However, new and improved parks, recreational facilities, and open space would be provided as part of the Project to offset the increase in demand on existing parks and open space areas created by the Project's new residents and employees. In fact, a total of 336.4 acres of parks, recreational facilities, and open space would be provided at the Project site, consisting of 239.7 acres of new parks, sports fields, and active urban recreation uses, and 96.7 acres of existing and improved parkland at the CPSRA.[985]

This analysis first identifies the proposed new facilities, and then analyzes whether the increase in the use of parks would lead to the substantial physical deterioration or degradation of existing and proposed facilities or result in the need for new or expanded facilities.

[984] The impact statements provided in each technical section of the EIR differentiate between construction impacts and operational or development impacts, and all identified mitigation measures are contained in the impact analyses. In addition, Table ES-2 in the Executive Summary of this EIR also summarizes all impact statements, the level of significance before mitigation, any identified mitigation measures, and the level of significance after mitigation.

[985] For comparison purposes, the Project's proposed 336.4 acres of parks and open space would be greater than the 141.5 acres of public open space that was to be provided under the Hunters Point Shipyard Reuse Plan Final EIR (June 2000).

Proposed New Facilities

Overall, the Project would provide a substantial increase in the amount of developed, useable, high-quality parks, recreational facilities, and open space within the Project site. The Project would create a continuous network of interconnected recreational opportunities, promoting the use of the existing parks, such as the CPSRA, as well as the 239.7 acres of new parks, sports fields, and active urban recreation uses. The Project would provide a network of pedestrian and bike pathways that would connect Project uses to the adjacent neighborhoods and would ensure unrestricted public access to the parks and open space on the Project site and the Bay shoreline. Enhanced connectivity of on-site and off-site facilities and new neighborhood parks would allow integration of new and existing facilities into the citywide park network. The proposed bicycle and pedestrian pathways would facilitate dispersal of future demand, which would help to reduce the potential for localized physical deterioration. The improved connectivity would also direct regional users to proposed "destination" parks, parks designed to accommodate regional demand. In addition, the Project would provide a continuous series of waterfront parks from the northernmost part of HPS Phase II to the southernmost part of Candlestick Point.

In addition, proposed recreational facilities, such as paved athletic courts, plazas, and picnic areas, would also support a large number of users within a relatively small area. Recreational facilities proposed for the Project site also include a Sports Field Complex that would provide soccer/football, baseball, and volleyball fields, as well as warm-up fields, restrooms, and food concessions. The parking area for the Sports Field Complex would support parking during stadium events, but would be covered with specially engineered soils and turf to allow dual-use of the parking lot for athletic fields. Recreational facilities would also include a mix of active and passive areas of open lawns, dog runs, play areas, community gardens, and court games. Moreover, improved park facilities would provide a waterfront promenade, ecological open space areas, concessions, restrooms, and other uses that would allow the site to support a large service population.

The discussion below identifies the specific new facilities that are planned within Candlestick Point and HPS Phase II. These facilities are also identified in Table III.P-1, above, and shown on Figure III.P-2. Some features, such as the Bay Trail improvements, span both areas of the Project site.

Candlestick Point

Candlestick Point would include an extensive network of parks, ranging from the CPSRA to smaller parks distributed throughout the neighborhood. The Candlestick Point parks would be connected to other neighborhoods and open spaces by way of pedestrian-friendly green streets.

- The 1.4-acre Alice Griffith Neighborhood Park would extend for several blocks near the center of the neighborhood as an extension of Egbert Avenue.
- Candlestick Point North would include a 3.1-acre Candlestick Point Neighborhood Park in the center of the district.
- The 1.1-acre Mini-Wedge Park in the Candlestick Point South district would serve as a primary connector between Candlestick Point and the CPSRA beach area.
- The Bayview Gardens/Wedge Park (2.5 acres) would serve as the 'commons' for the Candlestick Point development and link the residences to the CPSRA through an expansive view corridor. Specific programming would include an ecological garden, a main plaza, passive lawns, bioswale stormwater retention, and tot lots.

These parks would be connected to other neighborhoods and open spaces within the community by way of pedestrian-friendly green streets.

Candlestick Point State Recreation Area

Senate Bill 792 (SB 792) (refer to Appendix P2 [SB 792]) was signed by the Governor on October 11, 2009, and is codified as Chapter 203 of the Statutes of 2009. SB 792 repeals the *Hunters Point Shipyard Conversion Act of 2002,* the *Hunters Point Shipyard Public Trust Exchange Act,* and *Public Resources Code* Section 5006.8, and consolidates the key provisions of those statutes into a statute covering both the Candlestick Point area and HPS. The statute authorizes a reconfiguration of CPSRA coupled with improvements within the park and the provision of an ongoing source of park operation and maintenance funding. The proposed reconfiguration would remove about 29.2 acres from the current boundaries of CPSRA to be used for urban development, but would add about 5.7 acres not currently included in the CPSRA to The Neck, The Heart of the Park, and The Last Port areas of the CPSRA. These additional acres would widen the park in an area where the CPSRA boundary currently runs very close to the shoreline, creating a very narrow "pinch point" in the park. The additional acreage would thus create a buffer between development and the shoreline and improve the recreational value of this section of the park. In total, the area of the CPSRA (excluding the Yosemite Slough) would decrease by about 23.5 acres at the Candlestick Point site, from 120.2 acres to 96.7 acres. Table III.P-2 (Proposed Candlestick Point State Parks Land Agreement) presents the acreage of the areas proposed to be added to and removed from the park. Figure III.P-3 (Proposed CPSRA Reconfiguration) illustrates the area of CPSRA and City parkland to remain or to be removed, and the amount of CPSRA parkland to be added.

Table III.P-2 Proposed Candlestick Point State Parks Land Agreement

	Candlestick Point (acres)
Existing State Parkland at Candlestick Point	120.2
Area removed from State Parkland	(29.2)
Area added to State Parkland	5.7
Proposed State Parkland at Candlestick Point	96.7

SOURCE: Lennar Urban, 2009.

The portion of the park that is currently undeveloped or used for Candlestick Park stadium parking would be substantially improved to enhance overall park aesthetics and landscape ecology; reconnect visitors to the bay shoreline; and provide direct access to the bay for swimming, fishing, kayaking, and windsurfing. Proposed improvements include revegetation and landscaping, shoreline restoration and stabilization, infrastructure improvements (such as trails, pathways, and visitor facilities), a biofiltration pond to cleanse stormwater, the provision of habitat and opportunities for environmental education, 'Eco-Gardens,' and salt-marsh restoration. Although there would be a net decrease in the total area of the CPSRA, the recreational value of the new land with the improvements would increase the area's value.

Candlestick Point — Hunters Point Shipyard Phase II EIR

PROPOSED CPSRA RECONFIGURATION

FIGURE III.P-3

Specific areas of improvements in the CPSRA are discussed below. The discussion is presented to provide an overview of the conceptual design that is currently proposed. However, the ultimate configuration of each of these areas would be at the discretion of the California Department of Parks and Recreation through the ongoing planning process for the CPSRA.

Figure III.P-4 (Photographs of Existing CPSRA—Areas 1 and 2) through Figure III.P-7 (Photographs of Existing CPSRA—Areas 7 and 8) provide a representative photograph of each of the eight designated areas within the CPSRA that are described below (and illustrated by Figure III.P-2). Figure III.P-8 (Aerial View of CPSRA within the Project Site [Excluding the Yosemite Slough]) shows the existing unimproved and improved areas of the CPSRA and indicates where land would be removed or added relative to the existing CPSRA uses.

The Last Port

The area known as the "Last Port" (south of Harney Way) is presently designated within the CPSRA General Plan for a dinner restaurant, a family picnic rest stop, a parking area, trails, and native trees and shrubs with open grassy areas. Current facilities here include trails, parking, family picnic areas, and a restroom building. Landscape features include open meadow areas, berms planted with trees and shrubs, and a beach. The Project proposes changes to the CPSRA boundary in this area to add approximately 0.4 acre of additional land. In addition, the Last Port and The Neck would include a new beach area (refer to Figure II-21 [Natural Shoreline Recommended Work Map]).

The Project's landscape improvements for the "Last Port" area would focus on pedestrian circulation, safety, and wayfinding; intensifying areas for increased use; improving the overall park aesthetics and landscape ecology; and providing new overlooks and connections to follow the bay shoreline. Native grasslands and shorelines would be restored and stabilized, providing areas for activities such as strolling, picnics, kite flying, fishing, and direct access to implementation of the bay for swimming, kayaking, and windsurfing.

The Neck

The area known as "The Neck" is a narrow strip of land south of Jamestown Avenue between Harney Way and Hunters Point Expressway. This area is presently designated in the CPSRA General Plan for native trees and shrubs with open grassy areas, trails, picnicking, fishing, and windsurfing. Currently, a pier provides access for fishing and windsurfers use this area as a launching point, although no formal facilities for windsurf launching or lay-down areas are currently provided. The Project proposes reconfiguring the CPSRA boundary here to provide approximately 3.8 acres of additional land and a wider park along the shoreline, including a new beach area. Project facilities would include trails and overlooks, a parking lot, picnic areas, and a windsurf lay-down and launch area.

The Heart of the Park

The area known as "The Heart of the Park" is located south of the main park entry on Hunters Point Boulevard to the isthmus that connects to "The Point." This area is presently designated in the CPSRA General Plan for native trees and shrubs with open grassy areas, trails parking, picnicking, fishing, windsurfing, park administration, and restroom facilities. Existing facilities include the main vehicular

FIGURE III.P-8

entrance and kiosk, parking lots, trails, three restrooms buildings, and group and family picnic areas. Landscape features include open meadow areas, berms planted with trees and shrubs, and a sandy beach. The Project proposes changes to the CPSRA boundary in this area to add approximately 1.5 acres of additional land. The Project would retain and enhance much of the existing landscape structure. Planting and overall aesthetics would be improved, pedestrian pathways would be renovated and added, and program areas would be developed for greater use. Improvements are proposed to existing restrooms, picnic areas, and trails. Additionally, new overlooks, an interpretive amphitheater, and reconfigured park entrance and parking facilities are proposed.

The Point

The area known as "The Point" is located at the end of the peninsula at the southeastern portion of the park. This area is presently designated in the CPSRA General Plan as a "quiet area" with native trees and shrubs and open grassy areas, trails, family picnic areas, a fishing pier, and a restroom building. The Project proposes to revitalize the existing site with improvements focused on pedestrian circulation, safety, and wayfinding; intensifying areas for increased use; improving the overall park aesthetics and landscape ecology; and reconnecting visitors to the bay shoreline. Native grasslands and shorelines would be restored and stabilized and new overlook points are proposed.

Wind Meadow

The area known as "The Phase 4 Area" in the CPSRA General Plan would become the "Wind Meadow" after the Project's proposed CPSRA boundary changes. It is presently designated in the CPSRA General Plan for native trees and shrubs with open grassy areas, trails, parking, picnicking, restrooms, and a Cultural Program Center. Additionally, a theater is designated to accommodate a wide variety of events such as dance, music, and theater. The CPSRA General Plan also describes children's play areas, a kitchen, and food concession for this area. Existing development in this area is limited to landscape features, such as sculptural earthwork and walls, trails, grassland and overlooks. This area is currently used for strolling, dog-walking, fishing, and bird watching and is the home of "Main Beach" (illustrated by Photo 1 in this section). Proposed features here would include new trails, restrooms, picnic areas, restored natural landscape areas, waterfront overlooks, and access to the water.

The Last Rubble

Until recently, the Last Rubble area was characterized by large piles of rubble and debris, remnants of the site's previous use as a dumping ground. The California Integrated Waste Management Board completed a rubble and debris removal project in April 2009. As a result of this, the majority of the rubble and debris was either removed or crushed on site. The Last Rubble area is designated in the CPSRA General Plan for native trees and shrubs with open grassy areas, trails, and overlooks. The area currently contains crushed concrete rubble, trails, and a mix of native and non-native grassland and shrubland (refer to Photo 2). The area is used for strolling, dog-walking, and bird-watching. The Project proposes changes to the CPSRA boundary in this area. It would be transformed into a new center for the CPSRA, with a wide variety of new program elements. The park ranger station/visitor's center would be located here, as well as a "Great Meadow" for passive recreational activities. In addition, The Last Rubble would contain a new beach area. Other features here may include parking, picnic areas, overlook terraces, restrooms, and a restaurant/café.

Bayview Gardens North

This area, which is also known as the "Boat Launch," is currently used for stadium parking. It would be transformed by the Project into "Bayview Gardens North." It is presently designated in the CPSRA General Plan for group camping, trails, native trees and shrubs with open grassy areas, and a boat dock for group camps. Currently, the Boat Launch area includes an unused boat ramp, parking lot, and restroom building. Landscape features here include shoreline with riprap and pockets of wetland vegetation. Located between the Bay and the proposed Bayview Gardens/Wedge Park, the Bayview Gardens North area would offer the greatest integration of urban and naturalized open spaces anywhere in the open space system and would provide strong visual gateway to the state parks and the Bay. Bio-swales, stormwater 'Eco-Gardens,' marshland (including potential salt-marsh restoration), new boardwalks, and overlook/fishing piers are central features of this area. Refer to Figure II-21 for the location of the new marshland.

Grasslands South

This area, which runs north along the shoreline from the Boat Launch to Arelious Walker Drive, is currently used for stadium parking and is not available as recreation or open space land. The Project would create grasslands and other habitats and make the area a functioning part of CPSRA's open space. is presently designated in the CPSRA General Plan for parking, park administration, trails, native trees and shrubs with open grassy areas, fishing, and a boat access facility. The boat access facility is described as a four-lane boat launching ramp, 200 car-boat trailer parking spaces, and a concession-operated boat service station. A protective breakwater with docking for ferryboats is also described. Currently, this area is undeveloped and is used as parking for the Candlestick Park stadium. Existing landscape features include shoreline with riprap and pockets of wetland vegetation. A boat ramp and associated parking and restroom facilities have been constructed to the southeast of this area. The Project proposes to reconfigure the boundary of this area and to improve it with trails, overlooks, native grasslands, meadow lawns, marshland, and earthworks shaped to provide shelter from the wind and enhance views. Site features could include overlooks, interpretive play areas, restrooms, overlook terraces, and parking. Refer to Figure II-21 for the location of the new marshland.

The Bay Trail

As briefly described in Section III.P.3 (Regulatory Framework) discussion, and more extensively described in Section III.B, the Bay Trail is a planned recreational corridor that, when complete, will encircle San Francisco and San Pablo Bays with a continuous 400-mile network of bicycling and hiking trails. The Bay Trail would be incorporated into the design of new shoreline park facilities, such as the Waterfront Promenade, Heritage Park, Grasslands Ecology Park, and the CPSRA. It would tie together the entire waterside park system, providing clear connections to regional greenways and connections to waterways. The Bay Trail would encourage users from adjacent neighborhoods and other areas of San Francisco to utilize the new open spaces of the development and provide increased access to the shoreline. More specifically, the Project would include connections to the existing and new parks from the western boundary of Candlestick Point near the Harney Way/US-101 interchange, through the CPSRA, Yosemite Slough, and HPS Phase II shoreline to India Basin, connecting a gap in the Bay Trail that currently exists between the tip of the CPSRA to Indian Basin Flats. The footings for the Yosemite Slough bridge, under preliminary design, would cross the proposed extension of the Bay Trail under the Bay Trail Plan. Visitors utilizing the Bay Trail in the area of the bridge would be able to cross Arelious Walker Drive and pick up the Bay Trail on the other side of the bridge.

Other Parks and Open Space

- Boulevard Parks within the Project site. A hybrid of street and park, the Boulevard Park Streets bring broad fingers of green space into the urban neighborhoods, linking interior parks with bay-front parks. These streets have a strong pedestrian scale and quality, and serve as public 'front yards' for the neighborhoods. Broad landscaped medians or sidewalks (30-40' wide) are designed as mini-parks with garden seating areas. Boulevard Parks link the Alice Griffith and Central Candlestick communities with the CPSRA.
- Hillside Parks and Open Space within the Project site. The hillside parks and open space include the eastern 'tail' of Bayview Park and other hillside areas below Jamestown Road. The steeper areas and the flatter portion of Bayview Hill will be maintained in a more natural state.
- Yosemite Slough. While not located within the Project site except for the mouth of the slough, where the proposed bridge would be located, the Yosemite Slough is located directly adjacent to but outside of the Project site and is planned for restoration by the California State Parks and the California State Parks Foundation. The restoration will focus on providing new wetland habitat and environmental education opportunities. The proposed Yosemite Slough bridge would cross a small portion of the CPSRA on the southern side of the slough and pass along the edge of the eastern boundary of the CPSRA on the north side.

HPS Phase II

- Northside Park (12.8 acres), which would be located on the north shore of HPS Phase II, would offer a full suite of passive and active uses. The most active park uses are located at the southwestern portion of the park. This area includes community gardens, basketball, tennis, and volleyball courts and shade pavilion, children's playground, and restroom. The open-air African Marketplace would form an east-west promenade crossing the park, with looped pathways around the multi-use lawns providing additional multi-use space. To the northeast, the park takes on a more natural and passive character, with picnic/barbeque areas and shade shelters, and waterfront pathways.
- The Waterfront Promenade (29.5 acres) begins at the northern edge of the site and continues along the shoreline until terminating at the Waterfront Recreation Area described below. The promenade would provide evidence of the historic qualities of the industrial waterfront, which would be incorporated into tree bisques, seating areas, lawn panels, artworks, and interpretive gardens.
- Heritage Park (15.6 acres) would retain and reuse historic resources and materials as much as possible while utilizing modern design with industrial character. Children's play areas and areas of open lawn would be provided.
- Grasslands Ecology Park at Parcel E (44.9 acres) would contain native Eco-Gardens, passive lawns, native grasslands, windbreak groves, and landforms offering views of the bay and shoreline habitats. Site features could include group picnic areas, overlooks, a visitor/interpretive center, restrooms, and parking.

  Grasslands Ecology Park at E-2 (37.2 acres) would provide an open space area that includes picnic areas, grassy bird watching knolls, and overlooks. This passive recreation park would focus on views toward the Yosemite Slough Wetland Restoration area and provide opportunities for environmental education. The 44.9-acre Grasslands Ecology Park at Parcel E and the 37.2-acre Grasslands Ecology Park at Parcel E-2 on HPS Phase II are contiguous to CPSRA.
- The Sports Field Complex would include soccer/football, baseball, and volleyball fields, as well as warm-up fields, restrooms, and food concessions. The Sports Field Complex would be used for sporting events during day- and night-time hours. The surface of the fields would be seeded grass

above top soil with synthetic fibers and other base materials to support vehicle parking and tailgating for 49ers fans on game days. To prevent rutting and damage to the fields, the design will employ a fiber-reinforcement system that is incorporated into fast-draining, sandy soils.

- A Multi-Use Lawn area would provide event-day parking for events at the stadium. At other times, this large open space would provide for informal recreational activities, sporting, and other events as needed.

The Sports Field Complex and the Multi-Use Lawn both surround the proposed 49ers Stadium, providing parking for stadium-related events, as well as open space that would support a range of recreational activities, as described above. The surface of the fields would be seeded grass above top soil with synthetic fibers and other base materials to support vehicle parking.

- The Bay Trail would be incorporated into the design of the parks described above (refer to Figure III.P-2).
- The Waterfront Recreation Area would provide a flexible waterfront open space focused on small boat access could include education and interpretive facilities focused on San Francisco Bay.
- Boulevard Parks. A hybrid of street and park, the Boulevard Park Streets bring broad fingers of green space into the urban neighborhoods, linking interior parks with bay-front parks. These streets have a strong pedestrian scale and quality, and serve as public 'front yards' for the neighborhoods. Broad landscaped medians or sidewalks (30-40' wide) are designed as mini-parks with garden seating areas. Boulevard Park Streets connect the Hunters Point Hilltop community with Waterfront Park.
- Hillside Parks and Open Space Connection. A relatively small portion of the Hillside Park and Open Space located within HPS Phase II north of Crisp Road would provide a connection to the existing Hillside Parks and Open Space constructed in the Hunters Point Phase I project.
- Historic Landmark and Bay Naturalized Landscape. The landmark Re-Gunning Crane will be retained, providing a dramatic juxtaposition of the site's industrial history with the resurgence of nature at the Bay's edge. Trails and boardwalks would lead to overlook points providing visitors with opportunities to view Bay wildlife.

Overall, the Project would provide a substantial increase in the amount of developed, useable, high-quality parks, recreational facilities, and open space within the Project site. The Project would create a continuous network of interconnected recreational opportunities, promoting the use of the existing parks, such as the CPSRA, as well as the 239.7 acres of new parks, sports fields, and active urban recreation uses. The Project would provide a network of pedestrian and bike pathways that would connect Project uses to the adjacent neighborhoods and would ensure unrestricted public access to the parks and open space on the Project site and the Bay shoreline. Enhanced connectivity of on-site and off-site facilities and new neighborhood parks would allow integration of new and existing facilities into the citywide park network. The proposed bicycle and pedestrian pathways would facilitate dispersal of future demand, which would help to reduce the potential for localized physical deterioration. The improved connectivity would also direct regional users to proposed "destination" parks, parks designed to accommodate regional demand. In addition, the Project would provide a continuous series of waterfront parks from the northernmost part of HPS Phase II to the southernmost part of Candlestick Point.

In addition, proposed recreational facilities, such as paved athletic courts, plazas, and picnic areas, would also support a large number of users within a relatively small area. Recreational facilities proposed for the Project site also include a Sports Field Complex that would provide soccer/football, baseball, and volleyball fields, as well as warm-up fields, restrooms, and food concessions. The parking area for the Sports Field

Complex would support parking during stadium events, but would be covered with specially engineered soils and turf to allow dual-use of the parking lot for athletic fields. Recreational facilities would also include a mix of active and passive areas of open lawns, dog runs, play areas, community gardens, and court games. Moreover, improved park facilities would provide a waterfront promenade, ecological open space areas, concessions, restrooms, and other uses that would allow the site to support a large service population.

Potential for Increase in Use of Parks

Overall, the Project would provide approximately 336 acres of new and/or improved park land and recreational facilities to accommodate the estimated build-out population of approximately 24,465 residents within the Project site, consisting of 239.7 acres of new parkland, sports fields, and active urban recreation uses, and 96.7 acres of existing and/or improved parkland.[986] As previously described, the new parks would include a variety of parks, including neighborhood parks, destination parks, boulevard parks, hillside parks and open space connections, waterfront parks, and improvements to the CPSRA. Parkland connectivity would be provided along the waterfront from the northernmost portion of HPS Phase II (at Northside Park) to the southernmost tip of Candlestick Point (at The Last Port of the CPSRA) (refer to Figure III.P-2), an amenity that is not provided today.

The increase in parkland would provide a ratio of about 13.7 acres of parkland per 1,000 residents within the Project site. Although this ratio is lower than the current ratio of 108 acres per 1,000 residents, it is substantially higher than the ratio of 5.5 acres per 1,000 residents identified in the City General Plan and used as a benchmark for this analysis.

The project would also provide approximately 10,730 jobs, which could result in a daytime population of 35,195 (adding the resident population of 24,465, and assuming that no residents were also employees, which is unlikely). Counting the entire daytime population as a part of the population served by the parks on the Project site, the parks-to-population ratio would be 9.5 acres per 1,000 employees/residents, which still exceeds the benchmark ratio of 5.5 acres per 1,000 residents.

Overall, the increase in the resident and daytime population of the Project site would not lead to substantial physical deterioration or degradation of existing facilities, nor would it result in the need for new or expanded facilities. The Project would, therefore, not cause a significant impact and no mitigation is required.

- Despite the availability of sufficient park acreage on the Project site, new residents or employees of the Project site may also choose to use existing parks outside of the Project site (refer to the Setting section for discussion of nearby parks), which could result in the deterioration or degradation of those existing resources. Similarly, it is possible that existing residents of the nearby area could also use parks, recreational facilities, and open space provided by the Project. Thus, this analysis considers the parkland-population ratio for the broader Bayview community, including the Project site and adjacent areas.

[986] As mentioned in the Setting section, there are approximately 203 acres of existing parkland at the Project site, consisting of 120.2 acres for the CPSRA and 83 acres for the stadium. The stadium is not included in any of the resident-to-parkland calculations as useable parkland.

According to the 2000 US Census, the population of the BVHP area in zip code 94124 was 33,170.[987] The boundaries of zip code 94124 are formed by Cesar Chavez Street to the north, US-101 to the west, the Bay to the east, and the southern tip of the CPSRA to the south. Adding the Project population of 24,465 and the Project employee population of 10,730 to the existing (2000) population for Bayview was added to yields a total of 68,365 people potentially using the parks in the area.

There are a total of 181.2 acres of additional park resources in zip code 94124. The major parklands in this zip code area include Gilman Park (4.6 acres), Bayview Park (44 acres), India Basin Shoreline Park (11.8 acres), the new parks and open spaces proposed for HPS Phase I (36 acres)988, Le Conte Avenue Mini-Park (0.5 acre), Heron's Head Park (24 acres), Hill Top Park (3.4 acres), Adam Rogers Park (2.8 acres), Shoreview Park (0.5 acre), Bayview Playground (4.6 acres), Ridgetop Plaza (0.3 acre), Youngblood-Coleman Playground (6.1 acres), the Joseph Lee Recreation Center (1.9 acres), the Palou-Phelps Mini-Park (0.3 acre), and the Silver Terrace Playground (6.1 acres). The combined total of the Project parks (336.4 acres) and the other parks within zip code 94124 (181.2 acres) would be 517.6 acres, resulting in a parks-to-population ratio of 7.6 acres per 1,000 population. This exceeds the benchmark ratio of 5.5 acres per 1,000 population. Therefore, the increase in the Project's resident and employee population and the existing area population would not lead to substantial physical deterioration or degradation of existing and proposed facilities, nor would it result in the need for new or expanded facilities. The Project would, therefore, not cause a significant impact and no mitigation is required.

Park Phasing

The timing of Project development could result in a temporary increase in the use of parks, recreational facilities, and open space in a manner that would cause or accelerate the substantial physical deterioration or degradation of facilities if the development of residential and/or employment-generating uses were to occur in advance of the development of park and recreational facilities.

The conceptual development plan described in Chapter II would result in the development of residential units and parks during all of four stages of development. Figure II-17 shows the particular residential and park areas that would be developed or improved in each phase. Table III.P-3 (Residential Units and Park Acreage Provided during Each Stage of Development) outlines the number of residential units and the acreage of parkland to be provided during each stage of development, as well as the resulting park-to-population ratio for residents of the Project site. As this table indicates, at the end of each phase, the park-to-population ratio would be no lower than 13.8 acres per 1,000 residents. Table III.P-3a (Residential Units, Employment, and Park Acreage Provided during Each Stage of Development) identifies the resulting park-to-population ratio for residents and employees of the Project site. With the employee population added, the lowest park-to-population ratio at the end of a phase would be 9.6 acres per 1,000 residents/employees following the last stage of development.

[987] US Census Bureau American FactFinder, http://factfinder.census.gov/servlet/SAFFFacts?_event=Search&Geo_id=&_geoContext (accessed on October 11, 2009).
[988] This park development is expected to be completed in 2012.

Table III.P-3 Residential Units and Park Acreage Provided during Each Stage of Development

Stage of Development	*Residential Units*	*Population*	*Total Parkland (ac)*	*Park-to-Population Ratio (acres per 1,000 Residents)*
Existing	256	1,113[a]	120.2	108
Phase 1	3,160	7,363[b]	235.6	32.0
Phase 2	5,165	12,035[b]	246.9	20.5
Phase 3	7,670	17,872[b]	250.4	14.0
Phase 4	10,500	24,465[b]	336.4	13.8

a. Refer to Table III.C-1 (Existing Population [2005]) in Section III.C (Population, Housing, and Employment). This population correlates to the total number of households in the Traffic Analysis Zone, which includes more than the 256 households located in the Candlestick portion of the Project site (e.g., 292). It is likely, therefore, that the population within the Candlestick portion of the Project site is less than 1,113, which would only increase the existing park-to-population ratio.
b. Calculated as 2.33 people per residential unit.

Table III.P-3a Residential Units, Employment, and Park Acreage Provided during Each Stage of Development

Stage of Development	*Residential Units*	*Population*	*Total Parkland (ac)*	*Park-to-Population Ratio (acres per 1,000 Residents)*	*Employees*	*Park-to-Population Ratio (acres per 1,000 Residents & employees)*
Existing	256	1,113[a]	120.2	108	—	201.5
Phase 1	3,160	7,363	235.6	32.0	2,346	24.3
Phase 2	5,165	12,035	246.9	20.5	7,474	12.7
Phase 3	7,670	17,872	250.4	14.0	10,595	8.8
Phase 4	10,500	24,465[b]	336.4	13.8	10,730	9.6

a. Refer to Table III.C-1 (Existing Population [2005]) in Section III.C (Population, Housing, and Employment). This population correlates to the total number of households in the Traffic Analysis Zone, which includes more than the 256 households located in the Candlestick portion of the Project site (e.g., 292). It is likely, therefore, that the population within the Candlestick portion of the Project site is less than 1,113, which would only increase the existing park-to-population ratio.
b. Calculated as 2.33 people per residential unit.

During a given phase, however, park construction could lag behind residential development, leading the parkland-to-population ratio to drop below an acceptable level. Moreover, the development plan is conceptual, and could be modified during the entitlement and development process. Mitigation measure MM RE-2 would ensure that the parks and recreational amenities are constructed as residential and employment-generating uses are developed.

MM RE-2 *Phasing of parkland with respect to residential and/or employment-generating uses. Development of the Project and associated parkland shall proceed in four phases, as illustrated by Figure II-16 (Proposed Site Preparation Schedule) of Chapter II (Project Description) of this EIR. To ensure that within each phase parks and population increase substantially concurrently, development shall be scheduled such that adequate parkland is constructed and operational when residential and employment-generating uses are occupied. The following standards shall be met:*

- *No project development shall be granted a temporary certificate of occupancy if the City determines that the new population associated with that development would result in a parkland-to-population ratio within the Project site lower than 5.5 acres per 1,000 residents/population, as calculated by the Agency.*

- *For the purposes of this mitigation measure, in order for a park to be considered in the parkland-to-population ratio, the Agency must determine that within 12 months of the issuance of the temporary certificate of occupancy, it will be fully constructed and operational, and, if applicable, operation and maintenance funding will be provided to the Agency.*

Implementation of mitigation measure MM RE-2 would ensure that adequate parkland is provided as residential and employment-generating uses are constructed and occupied, and, at no time, shall the parkland-to-population ratio fall below 5.5 acres per 1,000 residents/population, as calculated by the City. Impacts related to parkland development with respect to development phasing would be less than significant.

Impact RE-3: Adverse Effects on Existing Recreational Facilities

Impact RE-3 **Implementation of the Project would decrease the size of CPSRA but would not, overall, have an adverse effect on the recreational opportunities offered by that park, nor would it substantially adversely affect windsurfing opportunities at the Project site. (Less than Significant) *[Criterion P.d]***

While the Project's reconfiguration of CPSRA would remove a net of 29.2 acres from the park, all of that acreage is degraded or unimproved (and not maintained) and does not provide substantial recreation opportunities to the community. Most of the land that would be removed from CPSRA is either currently used for stadium parking or is directly adjacent to Harney Way. The reconfiguration would add 5.7 acres of new parkland in The Last Port, The Neck, and The Heart of the Park, all areas that are currently developed and actively used that have high value as recreational resources. This additional acreage would widen the park at this important point, increasing its capacity for new users. Although there would be a net decrease in the total area of the CPSRA, that portion of the CPSRA that is currently developed and used for recreational purposes would be further expanded (by 5.7 acres) and improved.

Moreover, the Project would provide substantial improvements throughout the CPSRA. These improvements, which are described at length in the discussion of Impact RE-2, include revegetation and landscaping, shoreline restoration and stabilization, infrastructure improvements (such as trails, pathways, and visitor facilities), the provision of habitat and opportunities for environmental education, "Eco-Gardens," and salt-marsh restoration. The proposed Yosemite Slough bridge would cross a small portion of the CPSRA on the southern side of the slough and pass along the edge of the eastern boundary of the CPSRA on the north side. The area removed for bridge footings would impinge on approximately 300 feet or less (270 feet) through the CPSRA. On the south side, the bridge would extend Arelious Walker Drive through a portion of the CPSRA. Persons using the Bay Trail would be able to cross Arelious Walker Drive and easily access the opposite portion of the CPSRA. Thus, while the road and bridge approach on the south side of the slough would cross the CPSRA, it would not act as a physical barrier preventing use of the entire CPSRA. While the proposed road and bridge would cut through the open space in one location, the majority of the restored Slough area would remain unaffected and available for its intended use. Figure III.P-8 shows the existing unimproved and improved areas of the CPSRA and indicates where land would be removed or added relative to the existing CPSRA uses. These improvements would turn portions of the Park that are used for Candlestick Park stadium parking or are undeveloped and underutilized into functional parts of the CPSRA and of the Project's overall network of parks; see, for example, the descriptions above of The Last Rubble and The Wind Meadow. Currently improved parts of the CPSRA, such as The Heart of the Park, The Point, The Neck, and The Last Port, would also be improved. Overall, the reconfiguration and improvements would

enhance park aesthetics and landscape ecology; provide connections throughout the CPSRA and the other Project parks; and provide direct access to the Bay and the Bay shoreline for walking, swimming, fishing, kayaking, and windsurfing. The Project's proposed reconfiguration of the CPSRA therefore would not adversely affect the park's existing recreational facilities and opportunities.

The improvement and development of the CPSRA is expected to increase usage of CPSRA by visitors from outside the immediate Project vicinity (increased usage by the Project population and nearby residents is discussed above in Impact RE-2). While the number of additional visitors cannot be accurately predicted at this time, the Project's improvement will increase the amount of land at CPSRA that provides recreational opportunities (as discussed above), and will thus enable the park to accommodate the new demand. Moreover, the agreement between CDPR and the City or the Agency, providing for the reconfiguration of CPSRA, would also provide substantial funding for operation and maintenance of the park. This funding would further enable the park to accommodate increased demand.

Increased visitation to CPSRA would not significantly and adversely affect the park's existing recreational facilities and opportunities. A less-than-significant impact would occur, and no mitigation is required.

Windsurfing Analysis

As noted above, CPSRA is currently used by windsurfers as a launching point, and the Project proposes enhanced direct access for windsurfers. A Technical Memorandum for Wind Conditions (Technical Memorandum) was prepared for an adjacent development (Executive Park) to study the wind conditions at a windsurfing launch site at the CPSRA.[989] This document is included in Appendix P1. The Project was specifically considered in the Technical Memorandum as part of the cumulative development scenario that was analyzed for Executive Park. Wind direction is important in that an adverse direction can make it more difficult to launch, to reach a desirable sailing area, or to return to the launch site. Wind is necessary to launch and land, but if winds are too strong at the launch site, beginners and less-skilled windsurfers could find it difficult to do either.

There are no specific criteria for minimum or maximum wind speeds needed to support "good" windsurfing. If a project were to cause substantial wind speed reductions or increases over much of a major windsurfing area or at an irreplaceable launching or landing site, the utility of the CPSRA and Bay as an important windsurfing area could be affected.

The Technical Memorandum studied wind conditions at a launch site at CPSRA (in The Neck area) and in a 55-acre portion of the Bay south of the launch site. The study found that development in the cumulative scenario, which includes the Project, generally results in wind speed changes near the shoreline (generally within 300 feet) ranging from no change to a 10 to 20 percent decrease in wind speed. Approximately 7 acres near the shoreline would experience a decrease of 10 to 20 percent in wind speed; approximately 36 acres of the Bay would experience a decrease of five to 10 percent; and approximately 12 acres of the Bay would experience a decrease of less than five percent. The majority of the windsurfing test area (as identified in the Technical Memorandum) would not be substantially affected (e.g., a 10 percent decrease or less in wind speed). The Project would not significantly and adversely affect existing windsurfing opportunities at the CPSRA. A less-than-significant impact would occur, and no mitigation is required.

[989] Environmental Science Associates, *Potential Wind Conditions at Executive Park Development,* May 4, 2009.

Cumulative Impacts

The geographic context for an analysis of cumulative impacts to recreational resources is the City of San Francisco. The past and present development in San Francisco is described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable future development forecasts are based on projections of future growth and take into account projects going through the entitlement process, including the Yosemite Slough Restoration Project, Executive Park, Jamestown, Hunters Point Shipyard Phase I, Hunters View, and India Basin Shoreline, as well as additional growth in the City envisioned through 2030 (refer to analysis below).

The SFRPD maintain the City's parks, playgrounds, recreation centers, and open spaces throughout the City. The California Department of Parks and Recreation owns approximately 120.2 acres at CPSRA within the Project site. The National Park Service operates approximately 619 acres of parkland within the City as part of the Golden Gate National Recreation Area (GGNRA), including Alcatraz Island, Crissy Field, the Presidio, Fort Mason, and Ocean Beach.

The City's Recreation and Park Acquisition Policy recognizes that the localized neighborhood service populations' need for parks and recreational facilities vary based on demographic characteristics. The cumulative projects in San Francisco could include recreational facilities or would be required to improve or expand existing recreational facilities. Any potential impacts resulting from the construction or improvement of new or existing park and open space facilities provided by cumulative development would be specific to the particular project being constructed, its local context, and the specific construction impact. For example, the Recreation and Park Acquisition Policy includes a criterion that land purchased by the SFRPD that has a record of hazardous or toxic contamination must by fully remediated by the seller prior to acquisition. The Department of Toxic Substances Control has adopted a similar policy requiring land covenants at hazardous materials sites prior to redevelopment of those sites for recreational and other uses. Additional mitigation measures would likely be required to reduce construction-related significant impacts to air quality, traffic, noise, or other affected environmental resources resulting from construction of cumulative recreational facilities. As noted, above, construction activities associated with the proposed parks and recreational facilities of the Project would be temporary and, further, mitigation measures are identified in this EIR to reduce significant impacts, although not always to a less-than-significant level. A discussion of cumulative project-related construction impacts, including those associated with the construction of parks and recreational facilities is provided in the applicable sections of this EIR. (Refer to Section III.D, Section III.H, Section III.I, Section III.J, Section III.K, and Section III.M for the cumulative analysis and conclusions.)

Development of cumulative projects, but not the Project, would result in the increased use of existing neighborhood and regional parks and other recreational facilities by the total estimated City population of 892,335 persons in 2030 (refer to Section III.C).[990] If no new parks or recreational facilities were built in

[990] As discussed in Section III.C (Population, Employment, and Housing), the City recently developed citywide planning projections that would capture Citywide growth expected by 2030 considering the ABAG Projections 2009 target, but also taking into account local knowledge of projects currently in various stages of the entitlement process. Specifically, the 2030 population projection of 916,800 included the Project and two other large development programs currently undergoing environmental review (Treasure Island and Park Merced). To determine the 2030 population in the absence of the Project, this analysis subtracts the Project population of 24,465 from that projection.

San Francisco by 2030 and the inventory were to remain at approximately 5,886 acres[991] the ratio of acres of parkland per 1,000 residents would be approximately 6.6 acres.

At full build-out, the Project would increase the City's inventory of parkland to 5,989.2 acres[992], and its population to 916,800. The City's parkland-to-population ratio would remain approximately 6.6 acres per 1,000 residents. This is greater than the benchmark of 5.5 parkland acres per 1,000 population. In light of the Project's improvements, the City's stock of high-quality recreation land would be substantially increased, even as its parkland-to-population ratio remains the same.

Because there would be sufficient parkland and open space to adequately serve the projected City population in 2030 (including the Project and other growth envisioned by the City), even without the development of new parks and open space proposed by the Project, there is no significant impact to recreation as a result of development of the cumulative projects. Therefore, there is no cumulative impact to which the Project could contribute.

Refer to Section III.G (Wind) for a discussion of cumulative wind impacts.

[991] This assumption is conservative in that it is highly unlikely that there would be no additional development of parkland in the City. Future developments such as Treasure Island and Park Merced will be required to provide substantial amounts of parkland.

[992] The total of 6,102.2 acres of parkland consists of 5,886 acres of existing parkland (including the 120.2 acres of the CPSRA) plus the 216.2 new parkland acres provided by the Project. This figure assumes that the Project's new parkland is the only new parkland in the City between now and 2030. As explained above, that is very unlikely. The actual parkland-to-population ratio in 2030 is likely to be substantially higher than the 6.5 reported here.

SECTION III.Q UTILITIES

III.Q.1 Introduction

This section evaluates the effects on utilities and service systems related to implementation of the Project by identifying anticipated demand and existing and planned utility availability. For purposes of this EIR, utilities include water supply, wastewater conveyance and treatment, and solid waste collection and disposal. Stormwater[993] is discussed in Section III.M (Hydrology and Water Quality). The impacts of the Project related to electricity and natural gas demand and consumption are analyzed in Section III.R (Energy). This section analyzes electricity, natural gas, and telecommunications infrastructure relative to their ability to serve the Project site. This section identifies both Project-level and cumulative environmental impacts, as well as feasible mitigation measures that could reduce or avoid the identified impacts. The baseline conditions used in this analysis are identified under each utility discussion.

Data used to prepare this section include information obtained from the San Francisco Public Utilities Commission (SFPUC), the California Integrated Waste Management Board (CIWMB), the San Francisco Bay Regional Water Quality Control Board (RWQCB), and other regulatory agencies and service providers. Water demand was estimated in the *Water Supply Assessment for the Proposed Candlestick Point–Hunters Point Shipyard Phase II Project* (WSA) prepared by PBS&J for the SFPUC, included as Appendix Q1 (Water Supply Assessment). Additional information was obtained from several studies prepared on behalf of Lennar Urban, including the *Candlestick Point/Hunters Point Shipyard Infrastructure Concept Report* (2007) prepared by Winzler & Kelly Consulting Engineers; the *Low Impact Development Analysis* (2008) prepared by Winzler & Kelly; the *LID Stormwater Opportunity Study* (2009) prepared by Arup; the *Revised Water Demand Memorandum* dated October 15, 2009, and April 28, 2010,[994] by Arup, included as Appendix Q2 (Arup, Amendment to Water Demand Memorandum #16—Variant 2A [Housing/R&D Variant], April 28, 2010); Technical Memorandum from Hydroconsult Engineers dated October 2009 (Appendix Q3 [Technical Memorandum from Hydroconsult Engineers]); and the *CPHPS Infrastructure Plan* (October 2009) prepared by Winzler & Kelly and Arup.

Water

III.Q.2 Setting

Regional Water System

The Project site is served by the San Francisco Public Utilities Commission, which manages a complex Regional Water System (RWS), stretching from the Sierra Nevada Mountains to San Francisco Bay Area and serving 2.5 million residential, commercial, and industrial customers in the Bay Area and Sierra Nevada

[993] One threshold provided under the Utilities and Service Systems section of Appendix G of the CEQA Guidelines specifically relates to stormwater (Criterion XIV(c)); this threshold is addressed in Section III.M (Hydrology and Water Quality) of this EIR.

[994] An April 28, 2010, Addendum to the Water Demand Memorandum #16—Variant 2A (Housing/R&D Variant) (dated October 15, 2009) is included as Appendix Q2 of this C&R document.

foothills.[995] The RWS can be thought of as consisting of three integrated water supply and conveyance systems: Hetch Hetchy, Alameda, and the Peninsula systems.

The RWS provides wholesale water service to twenty-seven Bay Area water agencies located in Alameda, San Mateo, and Santa Clara Counties (wholesale customers), and also provides retail water for the residents, businesses, and industries within the municipal boundaries of the City and County of San Francisco (retail customers). In addition, the retail customers also include San Francisco International Airport and San Francisco County Jail in San Mateo County, the unincorporated Town of Sunol, Lawrence Livermore Laboratory, Castlewood development in Alameda County, and Groveland Community Services District in Tuolumne County.

Auxiliary Water Supply System

The Auxiliary Water Supply System (AWSS) is a separate and distinct water supply system for fire protection purposes only. Candlestick Point and HPS Phase II are not currently served by the AWSS. Currently, there is a planned extension of the AWSS on Gilman Street from Ingalls Street to Candlestick Point. The Project would connect to this extension and provide an AWSS loop within Candlestick Point. At HPS Phase II, the AWSS would be connected to the existing AWSS system at the intersection of Earl Street and Innes Avenue and at the Palou Avenue and Griffith Avenue intersection with a looped service along Spear Avenue/Crisp Road.

Sources of Water Supply

In Fiscal Year 2007/08 the RWS delivered an annual average of approximately 256.7 million gallons[996] of water per day (mgd), with approximately 85 percent of that water supply provided by the Hetch Hetchy system, which diverts water from the Tuolumne River. The balance (of approximately 15 percent[997]) comes from runoff in the Alameda Creek watershed, which is stored in the Calaveras and San Antonio reservoirs, and runoff from the San Francisco Peninsula, which is stored in the Crystal Springs, San Andreas, and Pilarcitos reservoirs (which also provide storage for water delivered from the Alameda and Hetch Hetchy systems). A small portion of retail demand is met through locally produced groundwater, used primarily for irrigation at local parks and on highway medians, and recycled water, which is used for wastewater treatment process water, sewer box flushing, and similar wash down operations. The SFPUC also retails groundwater (pumped from the Pleasanton well field) to the Castlewood development in Alameda County.

Water Supply Reliability Planning

To enhance the reliability of the RWS, improve dry-year supplies, diversify the water supply portfolio, and meet projected wholesale and retail demand through 2030, the SFPUC developed the Water Supply Improvement Program (WSIP), approved on February 28, 2005. Under the WSIP as originally developed, the SFPUC proposed to meet projected 2030 average daily purchase requests of 300 mgd in the RWS service area by increasing diversions from the Tuolumne River under its existing water rights and

[995] City and County of San Francisco, Public Utilities Commission (SFPUC) website, http://www.sfgov.org/site/frame.asp?u=http://www.sfwater.org/ accessed August 16, 2009.
[996] PBS&J, Water Supply Availability Study of City and County of San Francisco, October, 2009.
[997] Ibid.

developing 10 mgd of new local resources through a combination of additional conservation, water recycling and groundwater supply programs.[998] The WSIP proposed various water facility improvement projects to achieve stated public health, seismic safety, delivery reliability and water supply goals. The WSIP also included provisions for obtaining additional dry-year supplies. The Program Environmental Impact Report (PEIR) for the WSIP identified and analyzed potential impacts that would result from implementation of the WSIP, including the diversion of an additional 35 mgd annual average from the Tuolumne River, along with 3 variants and 6 alternatives, including various water supply combinations that could meet future demand. Impacts associated with the water supply decisions were analyzed at a project-level of detail. All facility projects, including construction of projects to implement proposed local water supply projects were analyzed at a program-level of detail. After certification of the FPEIR by the Planning Commission, on October 30, 2008, the SFPUC adopted a Phased WSIP option, which included the following program elements: (1) full implementation of all WSIP facility improvement projects; (2) water supply delivery to RWS customers through 2018 with an average annual target delivery of 265 mgd originating from the watersheds. This includes 184 mgd for wholesale customers and 81 mgd for retail customers; (3) water supply sources consisting of 265 mgd average annual from SFPUC watersheds, 10 mgd conservation, recycled water, and groundwater in San Francisco and 10 mgd conservation, recycled water, and groundwater in the wholesale service area; (4) dry-year water transfers coupled with the Westside Groundwater Basin Conjunctive Use project to ensure drought reliability; (5) re-evaluation of 2030 demand projections, RWS purchase requests and water supply options by 2018 and a separate SFPUC decision by 2018 regarding water deliveries after 2018; and (6) provision in the new Water Supply Agreement between the SFPUC and wholesale customers to impose financial penalties to limit water sales to an average annual 265 mgd from the SFPUC watersheds through 2018 (SFPUC Resolution No. 08-0200, October 30, 2008). Thus, under the Phased WSIP, SFPUC has voluntarily chosen to limit deliveries from the RWS surface water supplies, and by December 31, 2018, the SFPUC will reevaluate water demands and water supply options through 2030 in the context of then-current information.

The Phased WSIP would meet projected 2018 demand of approximately 285 mgd by capping deliveries from the RWS at 265 mgd, with 184 mgd allocated to wholesale customers and 81 mgd allocated to retail customers[999]. The remaining 20 mgd of demand would be met through water conservation, recycling and groundwater, with 10 mgd provided by wholesale customers and 10 mgd provided by local projects within San Francisco. Improved dry-year supplies would be provided via implementation of the Westside Groundwater Basin Conjunctive Use Project (in San Mateo County), and less than 2 mgd in water transfers. The 10 mgd of local supply committed to by the SFPUC upon adoption of the Phased WSIP would be provided through development of the local water supply improvements discussed below.

Local Water Supply Improvements

Groundwater

Early in its history, San Francisco made significant use of local groundwater, springs, and spring-fed surface water and in the 1930s pumping rates from the groundwater basin on the west side of the City were reported to be up to a total of 6 mgd. However, after the development of surface water supplies in the

[998] SFPUC, *Water Supply Improvement Program*, February 28, 2005.
[999] PBS&J, Water Supply Availability Study of City and County of San Francisco, October, 2009.[999] Ibid.

Peninsula and Alameda watersheds and the subsequent completion of the Hetch Hetchy system in the 1930s, the use of groundwater for the water supply system has been minimal.[1000]

San Francisco overlies all or part of seven groundwater basins, including the Lobos, Marina, Downtown, and South basins, located wholly within the City limits, and the Islais Valley, South, and Visitation Valley basins that extend south into San Mateo County. The portion of the Westside Basin aquifer located within San Francisco is commonly referred to as the North Westside Basin. Except for the Westside and Lobos basins, groundwater in the other basins is insufficient for municipal supply due to low yield[1001]. Local groundwater is used for irrigation purposes in some parks, as well as non-potable purposes at the San Francisco Zoo and Golden Gate Park.

SFPUC is currently studying implementation of the San Francisco Groundwater Supply Project (SFGSP), created as part of the WSIP, to expand use of the local ground water source to provide ongoing supply and to improve reliability during drought, maintenance conditions, earthquake, or other emergency. The SFGSP proposes the construction of up to six wells and associated facilities in the western part of San Francisco to extract up to 4 mgd of water from the North Westside Groundwater Basin for distribution in the City. The extracted groundwater would be treated, disinfected, and blended in small quantities with surface water supplies before entering the municipal drinking water system. The environmental review for this project is expected to begin in November 2009.

Recycled Water

From 1932 to 1981, San Francisco's McQueen Treatment Plant provided recycled water to Golden Gate Park for irrigation purposes. Due to regulatory changes, the City closed the McQueen plant and discontinued use of recycled water in Golden Gate Park. Currently, disinfected secondary-treated recycled water from the SFPUC's Southeast Water Pollution Control Plant is used on a limited basis for wash-down operations in the Combined Sewer Systems and is also provided to construction contractors for dust control and other construction purposes. Current use of recycled water for these purposes in San Francisco is less than 1 mgd.[1002]

In March 2006, the SFPUC updated the Recycled Water Master Plan (RWMP) for the City. The 2006 RWMP identified where and how San Francisco could most feasibly develop recycled water in the City and provided strategies for implementing the recycled water projects that were identified. The SFPUC plans to continue to diversify San Francisco's water supply portfolio by increasing the use of local water sources, such as recycled water, groundwater, water conservation, and desalination.

The San Francisco Recycled Water Program currently includes the Westside, Harding Park, and Eastside Recycled Water Projects. The proposed projects would provide up to 4 mgd of recycled water to a variety of users in San Francisco. Recycled water will primarily be used for landscape irrigation, toilet flushing, and industrial purposes. The Harding Park Project has completed environmental review, and the Westside Project is expected to begin environmental review in late 2009 or early 2010. The WSIP contains funding for planning, design, and environmental review for the San Francisco Eastside Recycled Water Project.

[1000] SFPUC, *2005 Urban Water Management Plan for the City and County of San Francisco*, December 2005.[1000] UWMP 2005.
[1001] PBS&J, Water Supply Availability Study of City and County of San Francisco, October, 2009.[1001] Ibid.
[1002] Ibid.

The Westside Recycled Water Project would provide recycled water to several sites on the west side of San Francisco. The system would produce recycled water at a proposed recycled water treatment facility in Golden Gate Park and deliver the water to the San Francisco Zoo, Golden Gate Park, and Lincoln Park Golf Course for landscape irrigation and for non-potable uses at the Zoo and Golden Gate Park, including at the California Academy of Sciences. SFPUC has begun the project-specific environmental review for this project.

In addition, the SFPUC has partnered with the North San Mateo County Sanitation District (NSMCSD) to propose the Harding Park Recycled Water Project, which would use recycled water from the NSMCSD located in Daly City, to irrigate the Harding Park and Fleming Park golf courses in San Francisco. Completion of these projects are anticipated by the end of 2013 and would produce 2 million gallons of recycled water to irrigate Golden Gate Park, Fleming and Lincoln golf courses, Harding Park, and the San Francisco Zoo, along with commercial customers. Daly City is expected to complete the project-specific environmental review for the Harding Park Recycled Water Project in 2009. Currently, the SFPUC is conducting a recycled water demand assessment on the Eastside of San Francisco. The assessment examines the potential uses of recycled water for irrigation, toilet flushing, and commercial applications.

Water Conservation

The SFPUC's demand management programs range from financial incentives for plumbing devices to improvements in the distribution efficiency of the system. The conservation programs implemented by the SFPUC are based on the California Urban Water Conservation Council's list of fourteen Best Management Practices (BMP) identified by signatories of the Memorandum of Understanding Regarding Urban Water Conservation in California, executed in 1991. Refer to the WSA (Appendix Q1) for an assessment of BMP progress to date.

In addition, the SFPUC is increasing its water conservation programs in an effort to achieve new water savings by 2018, consistent with the Phased WSIP. This program is based on the 2004 San Francisco Retail Water Demands and Conservation Potential report[1003] (Demand Report) that identified potential water savings and implementation costs associated with a number of water conservation measures. These new conservation programs include high-efficiency toilet replacement in low-income communities and water efficient irrigation systems in municipal parks. With this expanded conservation program, the SFPUC anticipates reducing gross per household consumption (which includes both residents and non-residents) from 91.5 gallons per day (gpd) to 87.4 gpd by 2018, which would result in a conservation supply potential of approximately 4.0 mgd annually.

Water Treatment Capacity

Water from the Hetch Hetchy system is delivered to customers without filtration since the quality of this water supply has warranted a filtration exemption.[1004] Water from the Alameda system is treated at the Sunol Valley

[1003] Hannaford and Hydroconsult, City and County of San Francisco Retail Water Demands and Conservation Potential, 2004.

[1004] Current regulations providing for a filtration exemption under the Safe Drinking water Act are found in Surface Water Treatment Rule (54 FR 27486, June 29, 1989), as amended by the Long Term 1 Surface Water Treatment Rule (67 FR 1812, January 14, 2002) and the Long Term 2 Surface Water Treatment Rule (71 FR 654, January 5, 2006). EPA granted a filtration exemption to SFPUC in September 1993.

Water Treatment Plant (WTP). Peninsula system water and any Hetch Hetchy or Alameda system water stored in Peninsula reservoirs is treated at the Harry Tracy WTP. These treatment plants have existing treatment capacities of 160 mgd and 120 mgd, respectively. To ensure treatment capacity into the future, the SFPUC is currently completing the environmental review of a proposal to upgrade the Sunol Valley WTP to reliably treat 160 mgd and increase the storage capacity of treated water at the Sunol Valley WTP. The Sunol Valley Water Treatment Plant (SVWTP) Expansion and Treated Water Reservoir project is located in an unincorporated portion of Alameda County in the Sunol Valley within the SFPUC's Alameda watershed. The SFPUC is also currently designing an expansion of the Harry Tracy WTP to reliably deliver 160 mgd, which would increase the total treatment capacity of the RWS to 320 mgd. The Harry Tracy WTP, located in unincorporated San Mateo County, California, near the Cities of San Bruno and Millbrae, proposes improvements including improving water quality, increasing water delivery capability, and strengthening facilities with seismic upgrades. These projects would further the delivery reliability goals identified by the SFPUC as part of the Phased WSIP by allowing the SFPUC to deliver water to meet winter demands during maintenance and emergency supply in the event of loss of the Hetch Hetchy system supply. In addition, SFPUC has initiated construction of the Tesla advanced disinfection treatment facility in Tracy, California, to provide advanced disinfection of water from the Hetch Hetchy system. When completed in 2011, the Tesla advanced disinfection treatment facility would be the nation's largest ultraviolet disinfection treatment plant.

Water Shortage and Dry-Year Planning

Prior to the late 1970s, droughts did not seriously affect the ability of the SFPUC to sustain full deliveries to its customers. However, as the 1987-1992 drought progressed and reservoir storage continued to decline, it became apparent that continued full deliveries could not be sustained. To provide some level of assurance that water could be delivered continuously throughout a drought (although at reduced levels), the SFPUC subsequently adopted a drought planning sequence and associated operating procedures that trigger different levels of water delivery reductions relative to the volume of water stored in SFPUC reservoirs.

Each year, during the snowmelt period, the SFPUC evaluates the amount of total water storage expected to occur throughout the RWS. If this evaluation finds the projected total water storage to be less than a level sufficient to provide sustained deliveries, the SFPUC may impose delivery reductions or rationing. The amount of the reduction is specified in contractual agreements between the SFPUC and wholesale customers, as detailed in the existing Water Shortage Allocation Plan (WSAP). The WSAP provides specific allocations of available water between the retail and wholesale customers associated with different levels of systemwide shortages. For retail customers, the provisions of shortage allocations are identified in the Retail Water Shortage Allocation Plan (RWSAP). Under the RWSAP, during a shortage of between 5 to 10 percent (Stage 1), SFPUC retail customers would experience no reduction in deliveries, but the SFPUC would issue a voluntary rationing request to customers, alert customers to water supply conditions, remind them of existing water use prohibitions, and provide education on, and possible acceleration of, incentive programs. For a shortage of between 10 to 20 percent (Stage 2), retail customers would experience a 1.9 percent reduction in retail deliveries. During Stage 2, all Stage 1 measures would be implemented, customers would receive a specific allotment of water, and if a customer's water use goes above their allotment, they would be subject to an excess use flow restrictor device and shut-off of water. For shortages in excess of 20 percent (Stage 3), all Stage 2 measures are implemented and additional reductions in retail allotments would be implemented, as determined by the SFPUC.

Current and Future Water Supplies

As discussed above, the Phased WSIP allocates 81 mgd to retail customers. In addition, approximately 3.5 mgd of groundwater is provided from local groundwater basins (to San Francisco parks, the San Francisco Zoo, Golden Gate Park, and Castlewood). Per the Phased WSIP, an additional 10 mgd would be provided from local groundwater and recycled water projects and from conservation measures that reduce demand. Table III.Q-1 (SFPUC Estimated Retail Water Supplies, 2010–2030) provides an estimate of retail water supplies between 2010 through 2030, which projects an increase from 84.5 mgd to 94.5 mgd.

Table III.Q-1 SFPUC Estimated Retail Water Supplies, 2010–2030

a. RWS surface water supplies are subject to reductions due to below-normal precipitation. This may affect dry-year supplies—model shows supply reduction occurs in year 2 of multiple-dry-year event (Source: SFPUC 2008 WSIP Phase Variant Supply limitation).
b. Groundwater serves irrigation to Golden Gate Park, SF Zoo, and Great Highway Median.
c. A Groundwater reserve of 0.5 mgd for irrigation purposes would remain as part of SFPUC's non-potable groundwater supply.
d. Castlewood current and projected use remains unchanged over 20-year planning horizon.
e. 2.0 mgd of groundwater treated and blended for Potable water supply purposes.
f. 2.0 mgd of new groundwater developed as part of the new local supply target.
g. 2.0 mgd of Recycled used for irrigation at Golden Gate Park, SF Zoo, Great Highway Median, and 2.0 mgd for other non-potable purposes.

Current and Future Water Demand

To update the water supply and demand estimates provided in the 2005 update of the Urban Water Management Plan (UWMP), the SFPUC developed a Water Supply Availability Study (WSAS, included as an attachment to Appendix Q1). The WSAS incorporates new water supply information (per the Phased WSIP) and generates new estimates of future water demand for San Francisco. The future water demand estimates are based on the most current population and employment estimates, which include the Project and other major development proposals not anticipated in the 2005 UWMP.

The new demand estimates also incorporate the results of the 2004 Demand Report, which analyzed water demands associated with each retail customer sector and included development of a water use model. The water use model accounts for demand at the end use level (such as individual toilets and showers), and established water use rates for specific units, including multi-family residential households and employees, the latter of which is used to estimate non-residential water demands. The WSAS used an average of these water use rates over the next 20 years (2010–2030) to establish a water use rate for multi-family residential households of 98.7 gpd, and a water use rate for employees of 42.42 gpd. With these unit rates, future water demand can be estimated from changes in the number of residential households and/or employees in San Francisco.

To update future water demand, the WSAS compared the estimates of residential households and employees used in the 2005 UWMP with new population and employment forecasts provided by the San Francisco Planning Department,[1005] which were designed to closely match the recently adopted Association of Bay Area Governments (ABAG) Projections 2009 target, and taking into account local knowledge of projects currently in various stages of the entitlement process. Updated water demand estimates were then generated, which included the increment of future growth that was not previously included in the 2005 UWMP estimates.

Estimates of water demand for major development proposals in San Francisco were based on information provided by project proponents (including Lennar Urban for the Project). The water demand estimates were independently reviewed by PBS&J and the SFPUC as part of the WSAS and the Water Supply Assessment (WSA) prepared for the Project and determined to be consistent with the demand rates developed for the 2004 Demand Report.[1006]

Table III.Q-2 (Estimated Average Annual Retail Water Demand) provides an estimate of total SFPUC Retail Water Demands from 2010 through 2030, which incorporates the most recent new residential development estimates from 2015 through 2030, and assumes some development not previously included in the 2005 UWMP estimates. Total retail water demand, including Project demand, is estimated to increase from 91.81 mgd in 2010 to approximately 93.42 mgd by 2030.

To assess the adequacy of current and projected future water supplies to meet estimated future demand, including the demand associated with major development proposals, including the Project, and other projected future growth (e.g., background growth from ABAG projections), the WSA included a comparison of retail water supply and demand. Table III.Q-3 (Comparison of Projected Water Supply and Demand for Normal, Single Dry, and Multiple Dry Years [mgd]) provides a comparison of the projected future retail water supply and demand in varying hydrologic conditions over the 20-year planning horizon through 2030.

[1005] San Francisco Planning Department, Projections of Growth by 2030, July 9, 2009 (included as Appendix A to the Water Supply Availability Study).

SOURCE: PBS&J, Water Supply Assessment for the proposed Candlestick Point/Hunters Point Shipyard Phase II project, October, 2009.

a. Residential Demands
b. Multiple Family Demand calculated as [2030 Incremental Growth of 0.24 mgd + (CP-HPS II 10,500 DU) 1.04 mgd + (TI-YBI 8,000 DU) 1.17 mgd + (Park Merced 8,900 total DU) 0.94 mgd = 3.40 mgd. With existing demand of 1.51 mgd at all three sites, net demand is (3.40 mgd – 1.51) 1.89 mgd.
c. Agriculture, Mining, Construction, Manufacturing, Transportation, Wholesale & Retail Trade, F.I.R.E., Services, Gov't including Builders – Contractors and Docks – Shipping, per 2009 ABAG Employment Projections updated dated from SF Planning (July 2009) Employment water demands calculated 42.42 gallons per employee per day.
d. Non-residential (jobs/employment) demands at major project sites were assumed to be contained in the 2009 ABAG Employment projections. Growth in demand is incrementally increased to reflect the growth in jobs over the 20-year planning horizon. To avoid double-counting the water demand associated with the 2009 SF Planning Non-Residential Employment Projections and the non-residential demand calculated in the developer estimates at each of the Project sites, the total water demand at each of the developments was adjusted to remove the non-residential demands. This study assumes all non-residential demand is accounted for in the 2009 SF Planning Non-Residential Employment Projections. Net change in water demand at the Project sites and the adjusted change in water demand without non-residential demand.
e. US Navy, SF International Airport, and other suburban/municipal accounts.
f. Lawrence Livermore Laboratories (0.8 mgd); Groveland CSD (0.4 mgd)
g. City Irrigation at Golden Gate Park, Great Highway Median and SF Zoo.
h. Castlewood Community demand served by wells in the Pleasanton well field.
i. Numbers are rounded according to standard rounding practices and may not add up due to hidden decimals; this table is consistent with Table 4-7 of the WSA.

Table III.Q-3 Comparison of Projected Supply and Demand for Normal, Single Dry, and Multiple Dry Years (mgd)

				Multiple Dry Year Event		
	Retail Supply and Demand	***Normal Year***	***Single Dry Year***	***Year 1***	***Year 2***	***Year 3***

SOURCE: PBS&J, Water Supply Assessment for the proposed Candlestick Point/Hunters Point Shipyard Phase II project, October, 2009.

a. RWS Supply SFPUC Water Supplies
b. Groundwater Uses for In-City Irrigation and Castlewood.
c. Total Retail Supply from SFPUC Water Supplies
d. SFPUC Retail Demand
e. The deficit shown in 2010 is the result of reducing the RWS supply to 81 mgd as per the Phased WSIP Variant, without full development of the additional 10 mgd of new supplies. 10 mgd of new sources would be developed and available for use in SF by 2015. However, SF Retail demand is currently lower than projected (FY07/08 use was 83.9 mgd). If SF Retail demands exceed the available supply of 84.5 mgd between 2010 and 2015, the Water Supply Agreement allows the SFPUC to purchase additional water from the RWS. If combined Retail and wholesale deliveries exceed 265 mgd, the SFPUC Retail customers would be required to pay an Environmental Surcharge for deliveries over 81 mgd (Total RWS deliveries in FY07/08 were 256.7 mgd).
f. Groundwater Supplies at Castlewood and In-City Irrigation.
g. WSIP Supply Sources (Recycled Water (4.0 mgd; Groundwater (2.0 mgd Existing and 2.0 from NWGWP, and WSIP Water Efficiency and Conservation (4.0 mgd).
h. Deficit occurs in year 2 and 3 of multiple dry year event, SFPUC implements its Drought Year Water Shortage Contingency Plans - RWSAP and WSAP would be required to balance supply and demand under this projected shortfall.

The deficit shown in 2010 is the result of the Phased WSIP, which restricts the SFPUC's allocation from the RWS supply to 81 mgd. Full development of the additional 10 mgd of new local supplies is projected to be available by 2015. However, current retail demand is much lower than the estimated 2010 demand in Table III.Q-3 (actual Fiscal Year 07/08 demand was 83.9 mgd).[1007] If retail demand exceeds the available RWS supply of 81 mgd between 2010 and 2015, and total RWS deliveries exceed 265 mgd between 2010 and 2015, the Water Supply Agreement allows the SFPUC to purchase additional water from the RWS for retail customers in the SFPUC service area by paying an environmental surcharge (total RWS deliveries in FY07/08 were 256.7 mgd, which is 8.3 mgd below the 165 mgd watershed delivery goal).[1008] After 2015, when the additional 10 mgd local supply is projected to be completed, the WSA shows no expected deficit in supply. The first phase of development of the Project is projected to be completed in 2019. It is expected, therefore, that the Project would not contribute to any deficiencies in supply experienced by the SFPUC between 2010 and 2015.

As shown in Table III.Q-3, after 2030, during the second and third year of a multiple dry-year period, the projected water supply would be slightly less than the estimated total retail demand, including demand associated with the Project. Thus, during multiple dry-year periods, the SFPUC would need to implement the provisions of the WSAP and RWSAP, which could include voluntary rationing or the curtailment of retail deliveries. With the implementation of the WSAP and RWSAP during multiple dry-year periods, existing and projected future water supplies would be sufficient to meet estimated future water demand.

III.Q.3 Regulatory Framework

Federal

Safe Drinking Water Act

The basic regulations governing the RWS are associated with the federal and California *Safe Drinking Water Act*s. The federal *Safe Drinking Water Act*, passed in 1974 and amended in 1986 and 1996, is the nation's primary law regulating drinking water quality and is implemented by the USEPA. The Act authorizes the USEPA to set national health-based standards for drinking water and requires many actions to protect drinking water and its sources, including rivers, lakes, reservoirs, springs, and groundwater wells. In addition to source water protection, the Act also provides for treatment, monitoring, sampling, analytical methods, reporting, and public information requirements. Implementation and enforcement of both the federal and California *Safe Drinking Water Act*s are under the jurisdiction of the California Department of Public Health (CDPH), Division of Drinking Water and Environmental Management. Drinking water regulations are set forth in the California Code of Regulations, Titles 17 and 22.

The amended federal S*afe Drinking Water Act* established phases of regulation and a number of regulatory deadlines to address drinking water requirements. This amended Act is implemented through subsidiary rules for regulation of specific contaminants or for monitoring or treatment requirements (USEPA 2007). The major USEPA drinking water regulations are listed below:

- Surface Water Treatment Rule
- Interim Enhanced Surface Water Treatment Rule

[1007] PBS&J, October 2009.
[1008] PBS&J, October 2009.

- Total Coliform Rule
- Stage 1 Disinfectants and Disinfection Byproducts Rule
- Stage 2 Disinfectants and Disinfection Byproducts Rule
- Long Term 1 Enhanced Surface Water Treatment Rule
- Long Term 2 Enhanced Surface Water Treatment Rule
- Variances and Exemptions Rule
- Lead and Copper Rule
- Radionuclides Rule
- Filter Backwash Recycling Rule
- Arsenic Rule
- Public Notification Rule

State

Water Conservation Projects Act

California's requirements for water conservation are codified in the *Water Conservation Projects Act of 1985* (Water Code Sections 11950–11954), as reflected below:

> Section 11952(a). It is the intent of the Legislature in enacting this chapter to encourage local agencies and private enterprise to implement potential water conservation and reclamation project.

Urban Water Management Planning Act

Section 10610.4 of the *California Urban Water Management Planning Act* specifies that "Urban Water Suppliers shall be required to develop water management plans to actively pursue the efficient use of available supplies." The SFPUC prepared and adopted the current Urban Water Management Plan in December 2005.

Water Code Sections 10910 et seq. (Senate Bill 610)

Effective January 1, 2002, the State of California, through Senate Bill 610 (SB 610), adopted a requirement that a city or county, and the associated public water system, prepare a Water Supply Assessment (WSA) for projects that meet certain criteria, including (1) a project creating the equivalent demand of 500 residential units, (2) a proposed shopping center or business establishment employing more than 1,000 persons or having more than 500,000 square feet of floor space, and (3) a commercial office building employing more than 1,000 persons or having more than 250,000 square feet of floor space. The Project meets the criteria for requiring a WSA because it meets all of the criteria listed above.

In an effort to streamline the water supply planning process within San Francisco, the SFPUC adopted resolutions in 2002 and 2006 to allow for all development projects requiring a WSA under SB 610 (qualifying projects) to rely solely on the adopted UWMP without having to go through the process of preparing individual WSAs. Because the Planning Department and Agency are currently engaged in planning for various proposed land development projects that go beyond the future developments considered in the 2005 UWMP update, the SFPUC concluded that its 2005 UWMP no longer accounted for every qualifying project in San Francisco. Therefore, until the 2010 UWMP is prepared, any qualifying projects not accounted in the 2005

UWMP, including the Project, would require preparation of a WSA that considers the SFPUC's current and projected supplies when compared to projected demands associated with new growth not covered in the 2005 UWMP. The WSA prepared for the Project is included in Appendix Q1.

Water Code Section 73504(b)

Water Code Section 73504(b) requires the SFPUC to assign higher priority to delivery of water to the Bay Area than to the generation of electric power.

Local

San Francisco Green Building Ordinance

To minimize the use and waste of energy, water, and other resources in the construction and operation of buildings, to provide a healthy indoor environment, and to reduce greenhouse gas emissions, in 2008 the Board of Supervisors adopted the Green Building Ordinance, which applies to newly constructed residential and commercial buildings and renovations to existing buildings. The Ordinance specifically requires a minimum reduction of 20 percent in potable water use, rising to a minimum of 30 percent reduction in potable water use by 2011 for high-rise residential buildings, mid-size commercial buildings, and large commercial buildings (as defined in the Ordinance). In addition, the Ordinance also requires a minimum reduction of 50 percent in the use of potable water for landscaping for high-rise residential, mid-size commercial, and large commercial buildings.

III.Q.4 Impacts

Significance Criteria

The CCSF and Agency have not formally adopted significance standards for impacts related to water, but generally consider that implementation of the Project would have significant impacts on this resource if it were to:

Q.a Require or result in the construction of new water treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects

Q.b Require new or expanded water entitlements and resources, if there are not sufficient water supplies available to serve the project from existing entitlements and resources[1009]

Analytic Method

The analysis in this section focuses on the potential for a change in existing and projected water use as a result of Project implementation. The primary resources used for this analysis include the following technical documents: *Candlestick Point / Hunters Point Shipyard Phase II Water Demand Memorandum* (October 15, 2009) prepared by Arup; *Water Supply Assessment for the Proposed Candlestick Point—Hunters Point Shipyard Phase II Project* (October 2009), prepared by PBS&J; *Water Supply Availability Study of City and County of San Francisco* (October 2009) prepared by PBS&J; *SFPUC Urban Water Management Plan* (December 2005),

[1009] This standard has been slightly modified from the text found in CEQA Guidelines, Appendix G, for ease of comprehension.

prepared for the SFPUC; and the *Final Programmatic Environmental Impact Report for the Water System Improvement Program* (October 2008), prepared by the San Francisco Planning Department.

This section includes an evaluation of whether existing water treatment facilities have sufficient treatment capacity to serve the Project, and whether an adequate and reliable source of water would be available to serve the Project, both of which require an estimate of water demand that would result from Project implementation.

Estimates of water demand for the Project were developed for Lennar Urban by Arup[1010] and are summarized in Table III.Q-4 (Project Water Demands Adjusted for Plumbing Codes and SF Green Building Ordinance [mgd]). Water demand for the Project was derived from an estimate of a historical benchmark demand, adjusted to account for current California Building Codes and an additional adjustment to account for the requirements of the San Francisco Green Building Ordinance, including the installation of ultra-low flow fixtures, the use of high-efficiency building equipment, and efficient landscape irrigation techniques. An independent analysis performed as a part of the WSA, which analyzed similar land uses and assigned a demand factor for each use, concluded that the demand estimates provided by Arup are consistent with SFPUC demand factors.

Table III.Q-4 Project Water Demands Adjusted for Plumbing Codes and SF Green Building Ordinance (mgd)

Land Use	*Candlestick Point*	*Hunters Point Shipyard Phase II*	*Total*
Residential	0.61	0.22	0.83

SOURCE: Arup, Candlestick Point–Hunters Point Shipyard Phase II Water Demand Memorandum, October 15, 2009.

a. Numbers are rounded according to standard rounding practices and may not add up due to hidden decimals used in this table. These entries are correct and consistent with Table 4-3 of the Water Supply Assessment.

Current land uses within the Project site include residential (Alice Griffith Public Housing) and recreational (including the Candlestick Point State Recreation Area [CPSRA] and Candlestick Park stadium), and a mostly vacant former shipyard. According to water meter readings from the Project site, current water use is approximately 0.3 mgd.[1011] Thus, based on a total estimated Project-related demand of 1.67 mgd (per

[1010] Arup, Candlestick Point/Hunters Point Shipyard Phase II Water Demand Memorandum, October 15, 2009.
[1011] PBS&J, October 2009.

Table III.Q-4) and current water use of 0.3 mgd from existing land uses, the net impact of the Project on water demand would be an increase of approximately 1.37 mgd.

Existing and projected future water supplies for SFPUC retail customers were compared with estimated future demand to determine whether water supplies would be sufficient to meet Project-related demands. The current status of ongoing water supply improvements was also assessed, to determine whether the anticipated future water sources would be available.

The current and planned treatment capacity of existing water treatment facilities was also reviewed to determine whether sufficient capacity exists to provide water treatment service to the Project.

Construction Impacts

Significance Criterion Q.a, above, indicates that the Project would have a significant adverse effect if it would require or result in the construction of new water treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects. The Infrastructure Plan for the Project would include a low-pressure water system, a reclaimed water system, an AWSS, and separate sanitary sewer and storm drainage facilities. Impacts of construction activities associated with the Project, including demolition and installation of new utility infrastructure, are discussed in Section III.D (Transportation and Circulation), Section III.H (Air Quality), Section III.I (Noise), Section III.J (Cultural Resources and Paleontological Resources), Section III.K (Hazards and Hazardous Materials), Section III.L (Geology and Soils), Section III.M (Hydrology and Water Quality), Section III.O (Public Services), and Section III.S (Greenhouse Gas Emissions) of this EIR. No new construction impacts beyond those identified in those sections would occur with construction of water conveyance or treatment infrastructure associated with the Project.

The water required for construction activities is assumed to be supplied by water trucks and/or existing sources. No construction-related impacts associated with the consumption of water would occur with the Project.

Operational Impacts

Although other sections of this EIR provide separate impact assessments for development at Candlestick Point and HPS Phase II, segregating the discussion of impacts on water treatment facilities and water supplies would not provide any additional meaningful information. Thus, for the purposes of clarity, this section only provides an assessment of Project impacts, which includes both components of the Project.

Impact UT-1: New or Expanded Water Entitlements and Resources

Impact UT-1 **Implementation of the Project would not require water supplies in excess of existing entitlements or result in the need for new or expanded entitlements. (Less than Significant) *[Criterion Q.b]***

Implementation of the Project would generate a total demand of approximately 1.67 mgd (per Table III.Q-4). This demand is based on an estimate of a historical benchmark demand, adjusted to account for current California Building Codes and the requirements of the San Francisco Green Building Ordinance, which would require the installation of ultra-low flow fixtures, use of high-efficiency building equipment, efficient landscape irrigation techniques, and provision of water-efficient plant materials. As

current water use from existing land uses at the Project site is approximately 0.3 mgd, the net effect of the Project on water demand would be an increase of approximately 1.37 mgd.

The Phased WSIP allocates 81 mgd from the RWS to retail customers. An additional 3.5 mgd of groundwater is provided from local groundwater basins. An additional 10 mgd would be provided from additional groundwater and recycled water projects, and from conservation measures that reduce demand (which the SFPUC identifies as a conservation supply). Total SFPUC retail water supply is estimated to vary between 93 and 94.5 mgd, depending on hydrologic conditions (per Table III.Q-1). Total future retail demand, including Project-related demand, is projected to increase from 91.81 mgd in 2010 to 93.42 mgd in 2030 (per Table III.Q-2). At the time of the first phase of Project implementation, sometime after 2015, SFPUC projects that adequate supply would be available to satisfy all retail demand, including Project-related demand, under normal conditions.

A comparison of total retail water supply to estimated water demand (per Table III.Q-3) shows that after 2030, during multiple dry-year periods, the total retail water supply would be slightly less than estimated total demand, including demand associated with the Project. With the implementation of the WSAP and RWSAP during multiple dry-year periods, which could include voluntary rationing or other water conservation strategies, existing and projected future water supplies could accommodate estimated future water demand, including the Project-related demand of approximately 1.37 mgd. As discussed in the WSA, the SFPUC has approved and has made substantial progress towards the implementation of the water facility improvement projects identified in the WSIP. The SFPUC has received voter approval to fund the Phased WSIP program and has initiated bond sales to fund implementation of individual projects, which are in various stages of implementation, including subsequent environmental review, design, or construction.[1012] Thus, there is substantial evidence that the SFPUC would implement the Phased WSIP facility projects described above, including the local water supply projects.

The local water supply projects, described in the setting, include: the San Francisco Groundwater Supply Project; the Westside Recycled Water Project; the Eastside Recycled Water Project, the Harding Park Recycled Water Project, and various conservation efforts. Collectively, these projects are estimated to provide approximately 10 mgd.[1013,1014] Of these projects, environmental review has been completed for the Harding Park Projects, and will soon be initiated for the other projects. The local water supply improvement projects were approved as part of the Phased WSIP and are included in the WSIP funding program. The SFPUC has initiated planning, environmental review, and design of several recycled water and groundwater projects and conservation programs are in place. Thus, there is substantial evidence that the additional water provided by those projects would be available to supplement retail water supplies.

[1012] Per the *Water System Improvement Program Quarterly Report, Q4, FY 2008/2009* (dated August 20, 2009), (prepared by the SFPUC), as of July 1, 2009, two (2) projects are in the Planning Phase, eleven (11) projects are in the Design Phase, six (6) projects are in the Bid and Award Phase, five (5) projects are in the Construction Phase, two (2) projects in the Close-Out Phase, eight (8) projects are completed, one (1) project has not been initiated, and eleven (11) projects have multiple active phases. Available at: http://sfwater.org/Files/Reports/01_RW_Program_Summary.pdf Accessed September 28, 2009.

[1013] San Francisco Planning Department, Final Program Environmental Impact Report, Water Supply Improvement Program, October, 2008.

[1014] SFPUC, Urban Water Management Plan, 2005.

As noted above, the SFPUC adopted the Phased WSIP, which phased implementation of the water supply program to provide an additional 20 mgd of supply to meet projected demand through 2018 and requires the SFPUC to re-evaluate water demands and water supply options by December 31, 2018 through 2030 to meet projected demand. The Project would not require water supplies in excess of existing entitlements or result in the need for new or expanded entitlements, and this impact is less than significant. No mitigation is required.

Impact UT-2: Construction of New or Expansion of Existing Water Treatment or Conveyance Facilities

Impact UT-2 **Implementation of the Project would not require or result in the construction of new or expanded water treatment facilities. The Project would require the expansion of an auxiliary water conveyance system to provide adequate water supply for firefighting to the Project site. (Less than Significant with Mitigation) *[Criterion Q.a]***

SFPUC determined in developing the WSIP that while it was meeting its core mission to serve San Francisco and its Bay Area customers with reliable, high-quality and affordable water, a long-term program was needed to reliably meet its mission in the future. The WSIP identified facility projects that would allow it to meet water supply, delivery reliability, seismic safety and water quality goals. In adopting the Phased WSIP, the SFPUC committed to implementing all of the identified facility projects, all of which underwent programmatic environmental review in the WSIP PEIR. As explained earlier, two of those projects would assist the SFPUC in meeting delivery reliability goals established for its two treatment plants. These projects are now undergoing project-level environmental review. It also identified a facility to provide for advanced disinfection of water from the Hetch Hetchy system, a project now under construction.

In addition, per SFPUC approval of the Phased WSIP, the SFPUC is proceeding to develop an additional 10 mgd of local supply from local recycled water and groundwater projects and additional conservation measures. The SFPUC is now in the planning and project-level review stage of these facility projects. Treatment requirements for these sources of water are included in the scope of those facility projects.

All of the projects identified above are planned for implementation irrespective of whether the Project is approved. As indicated in Table III.Q-3, water supply with the projects planned under the Phased WSIP would be sufficient in future years to meet normal demand, which includes Project demand. Implementation of the Project would not affect the treatment requirements of either of those sources of water. The groundwater and recycled water projects are in the planning and project-level environmental review phase now and are expected to be implemented before the first phase of the Project is expected to be completed. Implementation of water conservation measures, including those provided as part of the Project would reduce demand for water and would, therefore, not affect the treatment capacity of existing or proposed water treatment facilities.

As the current and planned facility projects under the Phased WSIP would provide for sufficient treatment capacity for the water to be supplied under the Phased WSIP and the Phased WSIP supply is sufficient to serve the Project, implementation of the Project would not require or result in the construction of new or expanded water treatment facilities, and this impact would be less than significant. No mitigation is required.

The Hunters Point Shipyard Reuse Environmental Impact Report (SCH #95072085, certified February 8, 2000) determined that the existing water system has insufficient pressure for adequate fire protection in certain portions of the Project site. The Project would expand the existing off-site AWSS by providing an AWSS loop at Candlestick Point that would connect to the planned extension of the existing off-site AWSS on Gilman Street from Ingalls Street to Candlestick Point. At HPS Phase II, the AWSS would be connected to the existing AWSS system at the intersection of Earl Street and Innes Avenue and at the Palou Avenue and Griffith Avenue intersection with a looped service along Spear Avenue/Crisp Road.

The following mitigation measure shall be implemented:

MM UT-2 *Auxiliary Water Supply System. Prior to issuance of occupancy permits, as part of the Infrastructure Plan to be approved, the Project Applicant shall construct an Auxiliary Water Supply System (AWSS) loop within Candlestick Point to connect to the City's planned extension of the off-site system on Gilman Street from Ingalls Street to Candlestick Point. The Project Applicant shall construct an additional AWSS loop on HPS Phase II to connect to the existing system at Earl Street and Innes Avenue and at Palou and Griffith Avenues, with looped service along Spear Avenue/Crisp Road.*

This AWSS would ensure the provision of adequate water for on-site fire-fighting purposes, and the Project would not require water supplies in excess of existing entitlements or result in the need for new or expanded entitlements for water to fight fires. The impact is less than significant with implementation of this mitigation measure.

Cumulative Impacts

The geographic context for an analysis of cumulative impacts to water resources is the service area of the Regional Water System (RWS) operated by the SFPUC. The past and present water supply and water treatment capacity in the RWS service area is described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. Reasonably foreseeable development includes future growth incorporated into the 2005 Urban Water Management Plan, and the updated demand projections included in the WSA (dated October, 2009) which included updated projections for San Francisco developed by San Francisco Planning Department (*Projections of Growth by 2030*, dated July 9, 2009).

Water in the Project area is provided by the SFPUC, which manages the RWS and provides wholesale water service to 27 Bay Area water agencies located in Alameda, San Mateo and Santa Clara Counties (wholesale customers), and retail water for the residents, businesses, and industries within the municipal boundaries of the City and County of San Francisco (and various other customers in San Mateo, Alameda, and Tuolumne Counties).

To enhance the reliability of the RWS, improve dry-year supplies, diversify the water supply portfolio, and meet projected wholesale and retail demand through 2030, the SFPUC developed the WSIP, which proposed a program of facility improvement and water supply improvement projects to accommodate a projected increased in annual average demand from 265 mgd to 300 mgd. The SFPUC subsequently adopted the Phased WSIP to implement the facility improvement projects that would meet public health, seismic safety, and delivery reliability goals, but with phased implementation of the water supply program, with an additional supply of 20 mgd from recycled water, groundwater and conservation projects proposed

to meet projected demand through 2018. By December 31, 2018, the SFPUC must re-evaluate water demands and water supply options and allocate available water supplies to meet the demand through 2030.

Per the Phased WSIP, retail water supplies to San Francisco, including the Project area, are comprised of deliveries from the RWS, groundwater, and the identified local water supply improvement projects. With these sources, retail water supplies are estimated to vary between 93 and 94.5 mgd (as shown in Table III.Q-1), depending on hydrologic conditions. Total retail water demand, including demand from the Project, several major development proposals (as discussed in the WSA), and background growth from ABAG projections and the 2005 UWMP is estimated to increase from 91.81 mgd in 2010 to approximately 93.42 mgd by 2030 (per Table III.Q-2).

When average annual retail water supply and demand are compared (in Table III.Q-3), after 2030, during multiple dry-year periods, the total retail water supply would be slightly less than estimated total demand, including the cumulative demand associated with the Project, major development proposals, and background growth. During multiple dry-year periods, the SFPUC would need to implement the provisions of the WSAP and RWSAP, which could include voluntary rationing or the curtailment of retail deliveries. With the implementation of the WSAP and RWSAP during multiple dry-year periods, existing and projected future water supplies could accommodate cumulative future retail water demand.

Implementation of the Phased WSIP would ensure sufficient water supply and water treatment capacity for the Project and estimated current and future retail demand. Provision of an AWSS on site and connection to the existing off-site AWSS by implementation of mitigation measure MM UT-2 would ensure adequate water for firefighting purposes. As no additional water supply or water treatment capacity is needed to serve the Project and projected future development beyond the supply identified under the Phased WSIP, the Project would not make a considerable contribution to a cumulative impact on water supply. The Project's cumulative impact on water supply is less than significant.

Wastewater

III.Q.5 Setting

San Francisco Combined Sewer System

Project Site

At Candlestick Point, the Candlestick Park stadium and Alice Griffith public housing site contribute to the Combined Sewer System, while the Candlestick Point State Recreation Area (CPSRA) and portions of the stadium parking lots have separate storm sewer systems. Stormwater at HPS Phase II does not flow to the City's Combined Sewer System, but is discharged to the Bay via separate stormwater system outfalls and overland flows.

Overview

Most stormwater runoff in the City is collected via a Combined Sewer System, managed by the SFPUC. This system combines stormwater runoff and wastewater flows in the same network of pipes (Combined Sewer System), conveying flows to facilities where they are treated prior to discharge to the Lower Bay or

Pacific Ocean through outfall structures along the shoreline. Discharges into the combined sewer are regulated under two individual National Pollutant Discharge Elimination System (NPDES) permits (waste discharge requirements [WDRs]) issued by the RWQCB as discussed in the Regulatory Framework. The City is divided into two major drainage areas: Oceanside and Bayside. The Project site is in the Bayside Drainage Area. This area is further divided into subbasins: North Shore, Channel, Islais Creek, Yosemite, and Sunnydale, all of which flow to the Southeast Water Pollution Control Plant (SWPCP). The North Point Wet Weather Treatment Facility (NPWWTF), located on Bay Street, operates only during wet-weather conditions to treat combined storm flows. Figure III.M-1 (Combined and Separate Storm Sewer System and Receiving Water Bodies) in Section III.M depicts the wastewater infrastructure that serves the City and the Project site, including an illustration of the areas that are currently served by the combined sewer and stormwater system and areas that are served by a separate sewer and stormwater system.

The capacity of the system, along with treatment and pumping capacities, is based on design criteria imposed by the RWQCB in the City's NPDES permits that were calculated for the purpose of protecting beneficial uses and achieving compliance with water quality standards, based on 70 years of annual rainfall data. The design criteria required construction of control facilities designed to store and treat enough wastewater to limit wet-weather discharges to an annual long-term average of 10, 8, 4, or 1, depending on the location of the discharge. In the Project vicinity, the wet-weather facilities have been designed and constructed to achieve a long-term annual average of 1 discharge to ensure that most wastewater receives secondary treatment (removal of settleable materials and partial removal of dissolved materials).

Dry Weather

During dry weather, wastewater and any dry-weather runoff (e.g., irrigation runoff, discharge from underground springs, or pipe leaks) from the eastern portion of the City are conveyed to the SWPCP, at Phelps Street between Jerrold and Evans Avenues, just northwest of the Project site (refer to Figure III.M-2 [Major Water Quality Features]). The SWPCP treats approximately 67 million gallons per day (mgd) during dry weather (approximately 80 percent of the City's total wastewater flow)[1015] to a secondary treatment standard, with a total capacity to treat 150 mgd. Secondary treatment uses pure oxygen to encourage growth of microorganisms that consume organic material and improve the purity of the wastewater. Wastewater is then put into a second round of settling tanks where the microorganisms are separated from the purified water. Effluent is disinfected and dechlorinated before discharge. Treated wastewater is then discharged through the Southeast Plant deep water outfall at Pier 80 or through the Quint Street outfall to the Islais Creek Channel.

The Combined Sewer System also includes the Bayside Wet Weather Facilities (BWWF), which consist of interconnected large underground rectangular tanks and tunnels with a series of baffles and weirs that are designed to remove settleable solids and floatables. During dry weather, the BWWFs transport combined stormwater and wastewater to the SWPCP.

[1015] San Francisco Public Utilities Commission, website: http://sfwater.org/mto_main.cfm/MC_ID/14/MSC_ID/117/MTO_ID/225, accessed July 22, 2009.

Wet Weather

At full wet-weather capacity, discharge at the Pier 80 outfall is maximized to 110 mgd; a blend of 100 mgd primary treatment and 10 mgd secondary treatment. The remaining 140 mgd receiving secondary treatment is discharged via the Quint Street shallow water outfall into Islais Creek Channel, which occurs an average of 600 hours per year.

The NPWWF is operated on a seasonal, as-needed basis to supplement the treatment capacity of the SWPCP. During larger storm events, excess flows that cannot be treated at the SWPCP are treated at the NPWWF, at 111 Bay Street, about 3.5 miles north of the Project site, which provides primary treatment and disinfection capacity for an additional 150 mgd of wet-weather flows. The treatment process at the NPWWF consists of primary sedimentation, clarification, floatables removal, disinfection, and dechlorination operations. It treats only wet-weather flow that consists of domestic and industrial wastewater mixed with stormwater runoff to a maximum capacity of 150 mgd. Treated flows from this facility are discharged through four deep-water outfalls, approximately 800 feet from the Bay shoreline and 18 feet below mean low water. Two of the deep-water outfalls terminate at the end of Pier 33, and two terminate at the end of Pier 35 on the northeastern Bay.

If the combined wet-weather flows exceed 150 mgd, the NPWWF can also treat an additional 100 mgd to a primary treatment standard (removal of settleable materials) plus subsequent disinfection and dechlorination.[1016] Wet weather flows that are treated to the primary standard (plus disinfection) are only discharged from the Southeast Pollution Control Outfall (Pier 80 outfall). San Francisco operates the only municipal wastewater facilities in California where, on an annual basis, approximately two-thirds of the stormwater runoff receives secondary treatment.

The Bayside Wet Weather Facilities, during wet-weather conditions, provide storage and treatment that is equivalent to wet weather primary treatment. During wet weather, the underground transport tunnels provide a total storage capacity of approximately 193 million gallons, while pumps continue to transfer combined wastewater and stormwater to the SWPCP. When the combined capacity of the SWPCP and the NPWWF is exceeded, the wet weather facilities retain storm flows for later treatment. The tanks allow floatable and settleable solid materials to be removed, similar to primary treatment processes. The materials retained in the storage and transport boxes are flushed to the treatment plants after storms.

This level of treatment meets the minimum treatment specified by the USEPA Combined Sewer Overflow Control Policy (CSO Policy) I50 FR 18688; April 11, 1994. In the event that the capacities of the SWPCP, the NPWWF, and wet weather facilities and storage structures are exceeded, the combined stormwater and sewage, after receiving the equivalent of wet weather primary treatment in the transport structures/boxes, is discharged into San Francisco Bay through any one of the 29 shoreline combined sewer overflow (CSO) structures. The outfalls associated with these CSO structures are very wide diameter pipes or box culverts. All solids that settle out in the storage/transport structures are flushed to the SWPCP after the rainstorm subsides.

During large storm events that cause the flow in the SWPCP to exceed 110 mgd, the complete filling of the treatment and storage capacities of the combined system cause excess flows to receive "flow-through

[1016] San Francisco Public Utilities Commission, 2008. *System Overview: Wastewater System Map.* Accessed online November 6, 2008 at: http://sfwater.org.

treatment," similar to primary treatment, to remove settleable solids and floatable materials. Flows are then discharged into the Bay, through any one of 29 CSO structures located along the City's Bayside waterfront from Fisherman's Wharf to Candlestick Point. The volume of a CSO discharge is a function of the storm intensity, storm duration, treatment rate, and available storage. CSO discharges typically consist of about six percent sewage and 94 percent stormwater.[1017] All solids that settle out in the storage/transport structures are flushed to the SWPCP after the rainstorm. There are six CSO structures in the vicinity of the Project site, in Yosemite Slough (South Basin) and Candlestick Cove. Figure III.M-2 in Section III.M shows the location of the CSO structures relative to the Project site.

Table III.M-1 shows a summary of CSO events that occurred in 2006 by discharges from the SWPCP, NPWWP, and BWWF. CSOs 040 through 043, which are adjacent to the Project site at Yosemite Slough and South Basin, had two CSO events per outfall. Treatment plant and CSO discharge points are shown on Figure III.M-2.

SFPUC Five-Year Wastewater Capital Improvement Program

The SFPUC launched the Wastewater Enterprise Interim Capital Improvement Program (Interim CIP) to address the immediate needs of San Francisco's wastewater system. These special projects are aimed at reducing flood risk, reducing wastewater odors, and improving treatment facilities. The Interim CIP addresses immediate critical needs while a long-term comprehensive capital plan is developed through the SFPUC's strategy review. Several Interim CIP projects are currently under construction, including the Channel Pump Station Improvements Project, Southeast Wastewater Treatment Plant Gas Handling Improvements - Phase 2, Oceanside Wastewater Treatment Plant Aging Infrastructure Project (Ventilation Improvements), and the Southeast Wastewater Treatment Plant Digester Odor Improvement - Phase 1.

Biosolids Environmental Management System

Biosolids are nutrient-rich organic materials resulting from the biological and physical treatment of wastewater in a treatment facility. San Francisco produces over 80,000 tons of biosolids a year that are transported to landfills in Alameda, Contra Costa, and Solano counties and two land application sites in Solano and Sonoma counties. To ensure environmentally sound disposal of biosolids, San Francisco has committed to prepare and implement an Environmental Management System (EMS), a voluntary program that would implement best management practices developed by the National Biosolids Partnership for odor, traffic, noise, and dust control, as well as the management of nutrients.

Bayside Systems and Facilities Operations Plan (2002)

The Master Plan for wastewater management completed in 1971 and modified in 1982 included the Bayside Transport/Storage System (Bayside System), consisting of expansion of the SWPCP, completion of the Bayside Core System (Griffith Pump Station and Yosemite Facilities), and construction of the Sunnydale Facilities, Mariposa Facilities, and Islais Creek Facilities, each of which was completed at various times but all by 1997. The City's NPDES permit (see Regulatory Framework, below) requires the City to prepare a systems and facilities Operations Plan that will:

[1017] City and County of San Francisco, Public Utilities Commission, and Port of San Francisco, 2009, op. cit.

- Maximize the volume of wastewater treated at either the Southwest treatment plant or the North Point Wet Weather Facility and discharged via deep water outfalls, consistent with the hydraulic and treatment capacities of the Discharger's storage, transport, and treatment facilities
- Ensure that all discharges from the diversion structures are first baffled to reduce floatables volumes

The Bayside Systems and Facilities Operations Plan describes the operations strategy that will be implemented to meet these objectives.

Project Site Wastewater System

Within Candlestick Point, the CPSRA and portions of the paved areas around the Candlestick Park stadium are served by separate wastewater and stormwater systems that drain to the Bay. Other portions of Candlestick Point, including the Alice Griffith Public Housing site and Candlestick Park stadium itself, currently contribute both wastewater and stormwater to the Combined Sewer System. The Project site is served by the Bayside Transport/Storage System in the southeast drainage area, which consists of the Hunters Point and Yosemite Transport Systems, Griffith Pump Station, and Sunnydale Transport and Pump Station Facilities.[1018] The storage/transport system holds the combined sewage and stormwater for later treatment at the wastewater treatment plant and is sized to accommodate both dry- and wet-weather flows. The storage/transport system provides some treatment by settling out solids and skimming of floatables. It is primarily used for storage during and after storms, but also provides storage in the event of a power failure. Catch basins collect stormwater runoff from City streets and discharge runoff into the Combined Sewer System. If the capacity of sewer pipes is exceeded during storms, excess flow is directed to the storage/transport boxes. Approximately one to ten times per year, a storm exceeds the capacity of the storage/transport box, and a discharge (CSO) occurs (refer to Section III.Q.5 [Setting]).

Sunnydale transport/storage box and pump station facilities are used only for wet weather. During wet weather, combined sewage is diverted from the gravity system to the transport system, with a storage volume of 5.7 million gallons, and then flows to the Sunnydale Pump Station, which has a capacity of 50 mgd.

Wastewater from Candlestick Point combines with flows from the Sunnydale Facilities in the Candlestick tunnel sewer prior to entering the Yosemite Transport System, then flowing to the Griffith Pump Station. The present average dry-weather flow through the Candlestick tunnel sewer entering the Yosemite Transport System is 6 mgd, including that from the Sunnydale watershed. The Yosemite Transport System and existing sewers have a storage volume of 11.5 million gallons and convey dry- and wet-weather flows from the Yosemite/Fitch area and Sunnydale area to the Griffith Pump station. The Griffith Pump Station receives all Sunnydale and Yosemite/Fitch discharges via gravity flow, which is then pumped to the Hunters Point tunnel sewer. Pumping capacities for the Griffith Pump Station are 10 mgd in dry weather and 120 mgd in wet weather. Dry-weather flows from the Griffith Pump Stations are relatively small.[1019] The South Basin and Hunters Point flows enter the SWPCP at Rankin Street.

[1018] City and County of San Francisco, Public Utilities Commission, Bayside Systems and Facilities Operations Plan, 2002.
[1019] City and County of San Francisco, Public Utilities Commission, Bayside Systems and Facilities Operations Plan, 2002.

Existing residential uses in Candlestick Point generate approximately 76,800 gpd[1020] of wastewater to the Combined Sewer System, while football games and other events at the Candlestick Park stadium generate up to 280,000 gpd[1021] of wastewater on event days (assuming a sold-out event). The volume of flows from the Alice Griffith Public Housing site and portions of the parking lots surrounding Candlestick Park stadium is unknown, as the SFPUC does not monitor volumes from individual land uses or areas. However, this flow would be included in the existing baseline flows routed to the SWPCP. Wastewater flows from the HPS Phase II site are minimal, as sewage lines are no longer in use in this area, with the exception of waste from the artists' studios. Based on meter data from January 2000 to August 2002, the HPS Phase II site generated an average of 0.154 mgd of wastewater flow. Thus, the majority of the HPS Phase II does not currently contribute notable wastewater to the Combined Sewer System. The Navy is removing the entire wastewater system at Hunters Point Shipyard as part of its environmental remediation program.

The Candlestick tunnel sewer has an average daily dry-weather flow of 2.5 mgd (1,736 gpm) and a design capacity of 50 mgd (34,722 gpm).[1022] The Hunters Point tunnel sewer has an average dry-weather flow of 6 mgd (including the 2.5 mgd from the Candlestick tunnel sewer) (4,167 gpm) and a design capacity of 120 mgd (83,333 gpm).[1023]

III.Q.6 Regulatory Framework

In the Project site, water resources policies are administered by several agencies, including the RWQCB; the State Water Resources Control Board (SWRCB), and the USEPA. Development of the Project is subject to the federal *Clean Water Act*, the California *Porter-Cologne Water Quality Control Act* (Porter-Cologne Act), applicable *Water Code* sections (plans and policies adopted by the SWRCB and RWQCB); and permitting and licensing requirements that occur during development review by the City and County of San Francisco.

Federal

Clean Water Act

The 1972 amendments to the federal *Clean Water Act* (CWA) prohibit the discharge of pollutants to navigable waters from a point source unless the discharge is authorized by a National Pollutant Discharge Elimination System (NPDES) permit. The RWQCB issue NPDES permits for stormwater and wastewater outfalls (point sources). Issued by the RWQCB in five-year terms, an NPDES permit contains discharge prohibitions, effluent limitations, and necessary specifications and provisions that ensure proper treatment, storage, and disposal of the waste. The permit often contains a monitoring program that establishes monitoring stations

[1020] Calculated as 256 units and 300 gallons per day, using the residential wastewater generation factor from the *Candlestick Point/ Hunters Point Shipyard Infrastructure Concept Report* (2007) prepared by Winzler & Kelly Consulting Engineers.
[1021] Calculated as 70,000 seats (in football configuration) and 4 gallons per seat day per day, per the wastewater generation rate for stadium uses in the Final Environmental Impact Report for the Los Angeles Coliseum Renovation Project, November 21, 2003 (SCH# 1990011065).
[1022] City and County of San Francisco, Public Utilities Commission, Bayside Systems and Facilities Operations Plan, 2002.
[1023] City and County of San Francisco, Public Utilities Commission, Bayside Systems and Facilities Operations Plan, 2002.

at effluent outfalls and receiving waters. NPDES permits are individually issued for point-source discharges, which usually refer to waste emanating from a single, identifiable location; a non-point source usually refers to waste emanating from diffuse locations. Stormwater is considered to be a non-point source if stormwater is discharged as overland flow, not from an identifiable location such as a pipe.

Discharges from the SWPCP, NPWWF, and BWWF, including CSOs, are regulated under the individual waste discharge requirements (NPDES Permit set forth in Order No. R2-2008-0007 and NPDES No. CA0037664). Stormwater discharges regulated under the NPDES program are discussed in Section III.M. Sheet/overland flow is a non-point source not regulated under the NPDES program.

State

Operation of the SWPCP is subject to regulations set forth by the SWRCB and California Water Code.

Local

San Francisco General Plan

The Environmental Protection chapter and the Community Facilities chapter of the *San Francisco General Plan* contain the following policies relating to wastewater:

Environmental Protection

Objective 3 Maintain and improve the quality of the Bay, ocean and shoreline areas.

Policy 3.3 Implement plans to improve sewage treatment and halt pollution of the Bay and ocean.

Community Facilities

Objective 10 Locate wastewater facilities in a manner that will enhance the effective and efficient treatment of storm and wastewater.

Policy 10.1 Provide facilities for treatment of storm and wastewater prior to discharge into the Bay or ocean. Locate such facilities according to the Wastewater and Solid Waste Facilities Plan.

III.Q.7 Impacts

Significance Criteria

The CCSF and Agency have not formally adopted significance standards for impacts related to wastewater, but generally consider that implementation of the Project would have significant impacts on these resources if it were to:

Q.c Require or result in the construction of new wastewater treatment or collection facilities or expansion of existing facilities, the construction of which could cause significant environmental effects

Q.d Result in a determination by the wastewater treatment provider that serves or may serve the project that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments

Q.e Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board[1024]

Analytic Method

Water use and wastewater flows are related. In general, wastewater is generated from indoor water uses, such as flushing the toilet, bathing, or cooking uses. Historical benchmark water demand by land use and end use were calculated for the Project and are described in Table 6 of the Water Demand Memorandum prepared by Arup on October 15, 2009 (refer to Appendix Q2). Sanitary sewer flows were determined utilizing wastewater generation percentages based on land use and end use water demand (refer to Table 7 of Appendix Q2). These factors were then adjusted to account for conformance with Green Building Ordinance requirements. Project wastewater estimates, shown in Table III.Q-5 [Project Wastewater Generation], were made based on estimated water demand in Table 7 of Appendix Q2 and consistent with PUC-recommended methodology. Parks and open space wastewater generation (runoff) is not included in this table, as it would not be conveyed off site to the sewer system.

Table III.Q-5 Project Wastewater Generation

Land Use	*Estimated Wastewater Generation Expressed as % of Water Demand (or as otherwise specified)*	*Candlestick Point (mgd)*	*Hunters Point (mgd)*	*Total Project (mgd)*
Residential	95%	0.58	0.21	0.79

Total		***0.71***	***0.47***	***1.18***

SOURCE: Arup, October 15, 2009.

Wastewater impacts were determined by comparing the estimated future wastewater flows to the capacity of off-site conveyance lines and the wastewater treatment plants to determine whether sufficient capacity exists or whether there is the need for additional wastewater conveyance or treatment systems. As discussed in Section III.M, stormwater from Alice Griffith Public Housing site, Candlestick Park stadium, and portions of parking lots surrounding Candlestick Park stadium would no longer contribute stormwater flows to the Combined Sewer System, which would increase the available capacity in the Candlestick tunnel sewer and Hunters Point tunnel sewers.

[1024] This standard has been slightly modified from the text found in CEQA Guidelines, Appendix G, for ease of comprehension.

As noted, above, the Yosemite transport system and existing sewers have a storage volume of 11.5 million gallons. Although the current volume of stormwater flows from the Project site is not known, the increase in wastewater flows associated with development at Candlestick Point would likely be offset by the reductions in stormwater flows that would result from the installation of a separate stormwater collection and treatment system at Candlestick Point. However, for the purposes of this analysis, no credit is taken for the eliminated stormwater flows from the Candlestick Point site.

The Project would construct separate stormwater and wastewater systems. Thus, during wet weather, stormwater from the Project site would not enter the Combined Sewer System; the only Project flows that would enter the Combined Sewer System, during both dry and wet weather, would be wastewater. For the purposes of this analysis, dry-weather peak flows from the Project would be the same as wet-weather peak flows and there is no need to analyze stormwater flow volumes from the Project relative to conveyance capacity in this section (refer to Section III.M), for a full analysis of stormwater conveyance and treatment). Therefore, Project dry-weather peak flows are assumed to be the same as wet-weather flows.

Peak dry-weather flow capacities can be calculated by multiplying the average gallons-per-minute flow by a peaking factor. For purposes of this analysis, a conservative peaking factor of 3.0 was used, which yields a maximum flow capacity of 5,208 gpm for the Candlestick tunnel sewer and 12,501 gpm for the Hunters Point tunnel sewer. The capacity of conveyance systems is analyzed by comparing maximum peak flows to the design capacity of the trunk line, expressed in gallons per minute (gpm). Wastewater treatment capacity is analyzed by comparing the daily treatment capacity of the plant, expressed in million gallons per day (mgd), with the existing conditions plus Project wastewater generation. Table III.Q-6 (Sewer Trunk Capacity and Project Maximum Peak Flows) illustrates the design capacity of the two sewer trunk lines serving the Project site, the existing average flow, the calculated existing maximum peak flow, the Project's contribution to the off-site conveyance infrastructure, and the remaining capacity (with the Project) of each of the two trunk lines. The Candlestick tunnel sewer flows into the Hunters Point tunnel sewer, and the data below reflect those combined flow volumes. However, because only conveyance capacity in the Candlestick tunnel sewer would require analysis, those data are also provided. Candlestick Point development discharges to the Candlestick and Hunters Point tunnel sewer, while discharges from the HPS Phase II site flow into the Hunters Point tunnel sewer only.

Several planning studies, referenced in the introduction to this section, were prepared to identify the wastewater demand of the Project and the associated conveyance infrastructure necessary for the Project. This analysis relies on those estimates. As wastewater generation is a function of potable water demand, the baseline year for purposes of the wastewater analysis is 2009 to coincide with the date of the WSA that has been prepared for the Project.

Appendix Q1 describes two different methods to calculate wastewater generation: (1) percentage of water demand, and (2) by end use (e.g., toilets, laundry, process water, etc.). Utilizing the first method of calculating wastewater flows, the Project would generate a total of 1.18 mgd of wastewater; utilizing the second method, the Project would generate approximately 0.98 mgd. These calculations both assume full compliance with the Green Building Ordinance. The impact analysis that follows uses the more conservative estimate of 1.18 mgd of wastewater generated by the Project.

Table III.Q-6 Sewer Trunk Capacity and Project Maximum Peak Flows

Sewer Trunk	*Design Capacity (gpm)*	*Existing Average Dry-Weather Flow[a] (gpm)*	*Existing Maximum Peak Dry-Weather Flow[b] (gpm)*	*Project Contribution—Maximum Peak Dry-Weather Flow[c] (gpm)*	*Remaining Peak Flow Capacity (gpm) With Project*
Candlestick tunnel sewer	34,722	1,736	5,208	1,479	28,035[e]
Hunters Point tunnel sewer	83,333	4,167[d]	12,501[d]	979	69,853[f]

SOURCE: Bayside Systems and Facilities Operations Plan, 2002.

a. Calculated as existing average dry-weather flow in mgd/24 hours/60 minutes x 1,000,000.
b. Calculated as existing average flow in gpm x peaking factor of 3.0.
c. Calculated as proposed average dry-weather flow in mgd/24 hours/60 minutes X 1,000,000 X peaking factor of 3.0.
d. These flows are *inclusive* of flows from the Candlestick tunnel sewer.
e. Calculated as design capacity less existing maximum peak flow less Project maximum peak flow, all in gpm. This calculation does NOT take credit for the existing uses at Candlestick Point (including Alice Griffith Public Housing, the RV park, and the stadium) that would be demolished on site and that currently contribute to the Candlestick tunnel sewer. Therefore, the actual remaining peak flow capacity of the Candlestick tunnel sewer with the Project would be somewhat greater than 28,035 gpm.
f. Calculated as design capacity less existing maximum peak flow less Project maximum peak flow, all in gpm. This calculation does NOT take credit for the existing uses on the HPS Phase II site that would be demolished that currently contribute wastewater flows to the Hunters Point tunnel sewer. Therefore, the actual remaining peak flow capacity of the Hunters Point tunnel sewer with the Project would be somewhat greater than 69,853 gpm.

As required by the Green Building Ordinance, high-rise and large buildings would be required to reduce water use by 30 percent in the year 2011 from a benchmark level adjusted for code. This requirement would result in a corresponding decrease in wastewater generation. Methods to achieve this standard could include, but are not limited to, low-flow plumbing fixtures, waterless urinals, and dual-flush toilets. Additional requirements for high-rise residential and large commercial buildings include water-efficient landscaping to reduce potable water use by 50 percent. Wastewater volume estimates take these Green Building Ordinance requirements into account. Peak dry-weather flow was calculated by multiplying the average gallons-per-minute flow by a peaking factor. For purposes of this analysis, a conservative peaking factor of 3.0 was used.

Construction Impacts

Significance Criterion Q.c, above, indicates that the Project would have a significant adverse effect if it would require or result in the construction of new wastewater treatment or collection facilities or expansion of existing facilities, the construction of which could cause significant environmental effects. Impacts of construction activities associated with the Project, including demolition and installation of new utility infrastructure, are discussed in Section III.D, Section III.H, Section III.I, Section III.J, Section III.K, Section III.L, Section III.M, Section III.O, and Section III.S of this EIR. No new construction impacts beyond those identified in those sections would occur with construction of wastewater conveyance or treatment infrastructure associated with the Project.

Operational Impacts

Impact UT-3: Wastewater Conveyance and Treatment

The following discussion is organized to first address the adequacy of the wastewater conveyance system for Candlestick Point and HPS Phase II separately, followed by a discussion of the adequacy of the wastewater conveyance system and treatment facilities for the Project.

Wastewater Conveyance

Impact of Candlestick Point

Impact UT-3a **Implementation of the Project at Candlestick Point would not require expansion of existing off-site wastewater conveyance facilities. (Less than Significant with Mitigation) *[Criterion Q.d]***

Dry-Weather Conditions

Wastewater flows from the Candlestick Point site enter the Candlestick tunnel sewer, combining with flows from the Sunnydale Transport System, and enter the Yosemite Transport Facilities. The flows proceed through the Griffith Pump Station and then through the Hunters Point sewer tunnel, eventually combining with flows from the Islais Creek Transport System and entering the SWPCP. As indicated by Table III.Q-6, the Candlestick tunnel sewer has an average dry-weather flow of 2.5 mgd (1,736 gpm) and a design capacity of 50 mgd (34,722 gpm). The existing maximum dry-weather peak flow from the Candlestick Point site into the Candlestick tunnel sewer is 5,208 gpm (existing average daily flow times peaking factor). Projected maximum peak flows from the Candlestick Point portion of the Project, based on a peaking factor of 3.0, would be approximately 1,479 gpm, as indicated by Table III.Q-6. The remaining peak flow capacity of the Candlestick tunnel sewer with the Project would be 28,035 gpm (design capacity less existing peak flow less Project peak flow contribution). This number does not take credit for the existing uses that would be demolished with implementation of the Project and would no longer contribute wastewater and stormwater flows to the Candlestick tunnel sewer, which means that the actual remaining peak flow capacity of the Candlestick tunnel sewer would be somewhat greater than 28,035 gpm.

The Hunters Point tunnel sewer has an existing average dry-weather flow of 6 mgd (4,167 gpm) and a design capacity of 120 mgd (83,333 gpm).[1025] Existing maximum peak flow in the Hunters Point tunnel sewer is estimated at 12,501 gpm (average daily flow times peaking factor). Projected maximum peak flows from Candlestick Point into the Hunters Point tunnel sewer, based on a peaking factor of 3.0, would be approximately 979 gpm, as indicated by Table III.Q-6. The design capacity of the Hunters Point tunnel sewer is 83,333 gpm. With the development of Candlestick Point, the Hunters Point tunnel sewer would have a remaining capacity of 69,853 (83,333 gpm design capacity less 12,501 gpm existing peak flow gpm less 979 gpm from Candlestick Point development) during peak dry-weather flow conditions. Therefore, the addition of approximately 979 gpm peak flow from the Candlestick Point development would be accommodated within the remaining capacity of the Hunters Point tunnel sewer.

[1025] City and County of San Francisco, Public Utilities Commission, Bayside Systems and Facilities Operations Plan, 2002.

The contribution of 1,479 gpm from the Candlestick Point development represents only 5 percent (1,479 gpm/29,514 gpm available capacity) of the available design capacity of the Candlestick tunnel sewer and 2 percent (1,479 gpm/70,832 gpm available capacity) of the Hunters Point tunnel sewer. This is a small percentage that could be accommodated by the existing infrastructure. No expansion of the existing off-site conveyance infrastructure would be required to accommodate wet-weather flows with the Project's contribution. As the existing conveyance infrastructure could accommodate the additional flows from the Candlestick Point development in addition to existing flows even during periods of peak flow conditions, no expansion of the off-site wastewater conveyance lines would be required as a result of development at Candlestick Point. The impact would be less than significant, and no mitigation is required.

Wet-Weather Conditions

While Project development at Candlestick Point would no longer contribute stormwater to the Combined Sewer System, Project wastewater discharges during wet weather would combine with off-site wet-weather flows and contribute to overall wet-weather discharge volume in the system. If wet-weather volumes were to exceed the capacities of the available conveyance facilities, a CSO could occur.

The Technical Memorandum prepared by Hydroconsult Engineers (Appendix Q3) analyzed the potential impact of the Project on wet-weather flows and CSO events. Model results included the frequency, volume, and duration of CSO from the Yosemite Basin, the only basin that would be impacted by the proposed development, and the total CSO volume for the entire Bayside. Based on Project acreages, Hydroconsult calculated a baseline of 5.3 million gallons per year CSO for the Yosemite Basin (based on one event per year) and a total Bayside CSO of 890 million gallons per year. The analysis determined that future sanitary flows from Candlestick Point to the City's Combined Sewer System would increase slightly, by 0.518 mgd, due to the new development. However, the separate wastewater and stormwater systems would result in a *decrease* in CSO volume, frequency, and duration of CSO in the Yosemite Basin (3.1 million gallons per year compared to the baseline of 3.1 million gallons per year) and decrease in overall CSO volume for the entire Bayside Drainage Area from 890 million gallons per year to 877 million gallons per year because stormwater from the Project site would no longer flow into the Combined Sewer System. The proposed diversion of wet-weather flows away from the combined system would offset the increase in dry-weather flows. Based on this analysis, the overall flows in the Bayside system during wet weather would be less than existing conditions with implementation of the Candlestick Point development. It is possible that a temporary increase in CSO volume could occur during wet weather if Project structures are occupied and contribute wastewater prior to completion of the Project's separate stormwater and wastewater infrastructure. To reduce this impact, the following mitigation measure shall be implemented:

MM UT-3a *Wet-Weather Wastewater Handling. Prior to approval of the Project's wastewater infrastructure construction documents for any new development, the Project Applicant shall demonstrate to the San Francisco Public Utilities Commission (SFPUC), in writing, that there will be no net increase in wastewater discharges during wet-weather conditions from within the Project Area boundary to the Bayside System compared to pre-Project discharges. This may be accomplished through a variety of means, including, but not limited to:*

- *Temporary on-site retention or detention of flows to the system*
- *Separation of all or a portion of the stormwater and wastewater system at Candlestick Point*

The contribution of the Candlestick Point development to the Bayside system represents a small percentage of its available capacity and would be accommodated by the existing infrastructure. Although development at Candlestick Point would increase wastewater flows (as intermittent flows from Candlestick Park stadium would be replaced by year-round flows from mixed-use development), the provision of separate stormwater and sewer systems would reduce overall wet-weather volumes to the Combined Sewer System. Mitigation measure MM UT-3a would ensure that there would be no net increase in wet-weather flows in the Combined Sewer System as a result of the Project that could result in a temporary increase in CSO volume. During wet weather, the temporary retention or detention of wastewater on site during wet weather or completion of the separate stormwater and wastewater systems for the Project would ensure that there would be no increase in the likelihood of a CSO event as a result of the Project. The impact on the Combined Sewer System would be reduced to less than significant.

Impact of Hunters Point Shipyard Phase II

Impact UT-3b **Implementation of the Project at HPS Phase II would not require expansion of existing off-site wastewater conveyance facilities. (Less than Significant with Mitigation) *[Criterion Q.d]***

Dry-Weather Conditions

HPS Phase II is served by separate wastewater and stormwater systems, and existing wastewater flows from this area are minimal, as sewage lines are no longer in use within HPS Phase II. Thus, HPS Phase II does not currently contribute substantial wastewater to the Combined Sewer System. Based on meter data from January 2000 to August 2002, the HPS Phase II site generated an average of 0.154 mgd (106.9 gpm) of wastewater flow. Thus, the majority of the HPS Phase II does not currently contribute notable wastewater to the Combined Sewer System.

Based on estimated potable water use and the generation factors described, above, development at HPS Phase II would generate approximately 0.6 mgd of wastewater flows during operation. Wastewater generated at HPS Phase II would be transported via the new or expanded conveyance systems within the Project site and existing mains to the SWPCP.[1026] Wastewater from the HPS Phase II site flows into the Hunters Point tunnel sewer. The Hunters Point tunnel sewer has an existing average dry-weather flow of 6 mgd (4,167 gpm) and a design capacity of 120 mgd (83,333 gpm).[1027] Existing maximum peak flow in the Hunters Point tunnel sewer is estimated at 12,501 gpm (average daily flow times peaking factor). Projected maximum peak flows from HPS Phase II into the Hunters Point tunnel sewer, based on a peaking factor of 3.0, would be approximately 979 gpm (0.47 mgd/24 hours/60 minutes x 1,000,000 times 3.0). The design capacity of the Hunters Point tunnel sewer is 83,333 gpm. With the Project, the Hunters Point tunnel sewer would have a remaining capacity of 69,853 gpm during peak dry-weather flow conditions. Therefore, the addition of approximately 979 gpm peak flow from the HPS Phase II development would be accommodated within the remaining capacity of the Hunters Point tunnel sewer.

[1026] *Candlestick Point/ Hunters Point Shipyard Infrastructure Concept Report* (June 30, 2009, revised July 22, 2009) prepared by Winzler & Kelly Consulting Engineers.

[1027] City and County of San Francisco, Public Utilities Commission, Bayside Systems and Facilities Operations Plan, 2002.

The contribution of 979 gpm from the HPS Phase II development represents only 1.2 percent of the total design capacity of the tunnel. This is a negligible percentage, and flows from the HPS Phase II site would be accommodated by the existing infrastructure. No expansion of the existing off-site conveyance infrastructure would be required to accommodate dry-weather flows with the contribution from development at HPS Phase II. As the existing conveyance infrastructure could accommodate the additional flows from the HPS Phase II development in addition to existing flows even during periods of peak flow conditions, no expansion of the off-site wastewater conveyance lines would be required as a result of HPS Phase II. The impact would be less than significant and no mitigation is required.

Wet-Weather Conditions

While Project development at HPS Phase would not contribute stormwater to the Combined Sewer System, Project wastewater discharges during wet weather would combine with off-site wet-weather flows and contribute to overall wet-weather discharge volume in the system. If wet-weather volumes were to exceed the capacities of the available conveyance facilities, a CSO could occur.

The Technical Memorandum prepared by Hydroconsult Engineers (Appendix Q3) analyzed the potential impact of the Project on wet-weather flows and CSO events. Hydroconsult determined that future sanitary flows from the HPS Phase II development to the City's Combined Sewer System would increase slightly by 0.236 mgd. However, the results of hydrologic modeling assuming the proposed separate wastewater and stormwater systems indicate a *decrease* in CSO volume, frequency, and duration of CSO in the Yosemite Basin and a decrease in overall CSO volume for the entire Bayside Drainage Area because stormwater from the Project site would no longer flow into the Combined Sewer System. The proposed diversion of wet-weather flows away from the combined system would offset the increase in dry-weather flows. In addition, mitigation measure MM UT-3a would ensure that there would be no increase in CSO flows as a result of the Project by providing temporary detention or retention of wastewater on site during wet weather or completion of the separate stormwater and wastewater systems for the Project. The impact on the Combined Sewer System would be reduced to less than significant.

Combined Impact of Candlestick Point and Hunters Point Shipyard Phase II

Impact UT-3 **Implementation of the Project would not require expansion of existing off-site wastewater conveyance or treatment facilities. (Less than Significant with Mitigation) *[Criterion Q.d]***

Wastewater Conveyance

Dry-Weather Conditions

The Candlestick Point development would discharge a maximum peak flow of 1,479 gpm to the Candlestick tunnel sewer, which has an existing unused capacity of 28,035 gpm in dry weather. This flow would combine with a maximum peak flow of 979 gpm from the HPS Phase II into the Hunters Point tunnel sewer. The total maximum peak Project flows of 2,458 gpm would combine in the Hunters Point tunnel sewer, which has an existing unused capacity of 69,853 gpm in dry weather. This represents 3.5 percent of the available capacity of the Hunters Point tunnel sewer, which could be accommodated by the existing off-site infrastructure.

Wet-Weather Conditions

Hydroconsult Engineers determined that the total net increase in wastewater from the Project site would equal 0.754 mgd, and that there would be a decrease in CSO volume, frequency, and duration of CSO in the Yosemite Basin and a decrease in overall CSO volume for the entire Bayside Drainage Area because stormwater from the Project site would no longer flow into the Combined Sewer System. The proposed diversion of wet-weather flows away from the combined system would offset the increase in dry-weather flows. Based on this analysis, the overall volumes in the Bayside system during wet weather would be less than under existing conditions with implementation of the Project. It is possible that a temporary increase in CSO volume could occur during wet weather if Project structures are occupied and contribute wastewater to the Combined Sewer System prior to completion of the Project's separate stormwater and wastewater infrastructure. Mitigation measure MM UT-3a would ensure that there would be no increase in CSO flows as a result of the Project by providing temporary detention or retention of wastewater on site during wet weather or completion of the separate stormwater and wastewater systems for the Project. The impact on the Combined Sewer System would be reduced to less than significant.

Wastewater Treatment

Based on estimated potable water use and utilizing the percentage factors as described in Table III.Q-5, development at Candlestick Point would generate approximately 0.71 mgd of wastewater. Development of HPS Phase II would generate approximately 0.47 mgd of wastewater. The SWPCP currently treats approximately 67 mgd during dry-weather conditions and has a capacity to treat 150 mgd to the secondary treatment standard. The net increase in dry-weather wastewater flows with the Project would represent only 1.4 percent of the remaining dry-weather treatment capacity (1.18 mgd/83 mgd) and 0.8 percent of the overall treatment capacity of the SWPCP (1.18 mgd/150 mgd).

The current remaining treatment capacity of the SWPCP would accommodate the increase in wastewater flows from the Project development. As noted, overall flows during wet weather would decrease, indicating that the proposed diversion of wet-weather flows away from the combined system would offset the increase in dry-weather flows, assuming completion of Project utility infrastructure prior to Project occupancy. Based on this analysis, the overall volumes in the Bayside system during wet weather would be less than under existing conditions with implementation of the Project. It is possible that a temporary increase in CSO volume could occur (which could affect the capacity of the SWPCP for treatment) during wet weather, as noted, above. Mitigation measure MM UT-3a would reduce this impact to less than significant by providing temporary detention or retention of wastewater on site during wet weather or completion of the separate stormwater and wastewater systems for the Project. Thus, the Project would not result in any net increase in CSO volume in the Bayside system during wet weather. A less-than-significant impact to existing off-site treatment facilities would occur.

Impact UT-4: Wastewater Treatment Requirements of the RWQCB

Impact UT-4 **Implementation of the Project would not exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board. (Less than Significant) *[Criterion Q.e]***

As discussed in Impact UT-3 above, the Project development would incrementally contribute wastewater during dry and wet-weather events to the Combined Sewer System operated by the SFPUC, but overall, wet-weather volumes would decrease in the Bayside system with construction of the Project's separate stormwater and wastewater systems. The SWPCP, the NPWWF, and the BWWF are required to comply with the WDRs set by the RWQCB, which specify the discharge requirements for those facilities.

As discussed in the Regulatory Framework above, the NPDES permit system requires that all existing and future municipal and industrial discharges to surface waters within the City be subject to specific discharge requirements. Wastewater from the Project would be treated at the SWPCP wastewater treatment plant and BWWF. The SFPUC, which operates the SWPCP wastewater treatment plant and BWWF, is required to comply with permit requirements set by the RWQCB, which specify the discharge requirements for the facility. These extensive requirements are codified in Order No. R2-2008-0007 for NPDES Permit No. CA0037664 and prohibit, among other things, exceedance of dry-weather flow of 84.5 mgd and discharge of any untreated wastewater to any waters of the United States, including the Bay. Compliance with any applicable permit requirements, as monitored and enforced by the SFPUC, would ensure that the Project would not exceed the applicable wastewater treatment requirements of the RWQCB. In addition, the Project would not cause the City to exceed the requirements of the NPDES permit for the reasons previously stated and because the flows during wet weather would actually decline compared to existing flows from the Project site. This impact would be less than significant. No mitigation is required.

Cumulative Impacts

The geographic context for an analysis of cumulative impacts to wastewater treatment and conveyance facilities is the wasteshed that utilizes the Candlestick Point and Hunters Point tunnel sewers and contributes wastewater to the SWPCP and potentially the NPWWF and BWWF during wet weather. The past and present development in the City is described in the Setting section of this chapter, representing the baseline conditions for evaluation of cumulative impacts. For wastewater conveyance, reasonably foreseeable development includes future projects that would be served by the Bayside Transport/Storage System, as described in Section III.Q.5 of this section. For wastewater treatment, the cumulative projects would include all reasonably foreseeable future development in the Bayside Drainage Area that would utilize the SWPCP, NPWWDF, and BWWF.

Wastewater Conveyance Capacity

Cumulative projects in the Bayside Drainage Area would contribute both additional wastewater and additional stormwater to the Bayside System, which could exceed its capacity. As noted above, the Bayside Systems and Facilities Operations Plan is intended to implement strategies to meet the objectives expressed in the Plan, which include maximizing the volume of wastewater treated at the SWPCP or NPWWF consistent with their capacities. Any cumulative projects that would result in wastewater and/or stormwater

flows that exceed the capacity of the Bayside system would be inconsistent with the objectives of the Operations Plan and would result in a potentially significant impact on wastewater conveyance.

The Project would construct a separate stormwater and wastewater system on site and would only contribute wastewater to the Bayside System. Peak-flow capacities of the Bayside System are adequate to convey the wastewater generated by the Project, which would only represent 3.5 percent of the remaining available capacity of the Bayside conveyance system. Wet-weather flow volumes would be reduced compared to existing conditions because the stormwater that currently flows from the Project site into the combined system would be offset by the proposed separated stormwater and wastewater system on site. Because there would be adequate dry-weather conveyance capacity to transport wastewater from the Project and because the total wet-weather volume in the Bayside system with the Project would be less than under current conditions, it would have no impact and, regardless of future contributions to CSOs from other projects, the Project's contribution would not be cumulatively considerable. Mitigation measure MM UT-3a would ensure that there would be no increase in CSO flows as a result of the Project by providing temporary detention or retention of wastewater on site during wet weather or completion of the separate stormwater and wastewater systems for the Project. The Project's cumulative impact would be less than significant.

Wastewater Treatment Capacity

Wastewater from the Project site is treated at the SWPCP. The SWPCP has a design capacity of 150 mgd to secondary treatment standards, with the ability to treat an additional 100 mgd during wet weather to primary treatment standards. The SWPCP currently processes an average flow of 67 mgd, with a remaining secondary treatment capacity of 83 mgd. Cumulative projects in the wastershed would contribute to the overall demand for wastewater treatment by the SWPCP.

The SWPCP can accommodate the maximum additional 1.18 mgd of wastewater generated by the Project without requiring any expansion of existing facilities. Development of cumulative projects within the wasteshed, including the Project, is not expected to generate additional quantities of wastewater beyond the current capacity of the SWPCP. The existing and future wastewater flows in combination with Project flows would not exceed the capacity of existing infrastructure and would not require or result in the construction of new or expanded wastewater conveyance facilities or expansion of existing facilities, other than those on site, for which construction impacts have been comprehensively analyzed in this EIR. Therefore, the Project's cumulative impact would be less than significant.

Compliance with Waste Discharge Requirements

The NPDES permit system requires that all existing and future municipal and industrial discharges to surface waters within the City of San Francisco be subject to specific discharge requirements. The Project would not result in the discharge of untreated wastewater to any surface waters. Operational discharges would be sent through the Project's on-site sewer system that connects to the City's Combined Sewer System. Wastewater generated at the Project site would ultimately be treated at the SWPCP. The SWPCP is required to comply with its associated waste discharge requirements, which set the levels of pollutants allowable in water discharged from any facility. Related projects would be required to follow all local and regional rules and regulations pertaining to wastewater treatment compliance. Consequently, there would be no cumulative problem to which the Project could contribute. The Project's cumulative impact would be less than significant with regard to compliance with waste discharge requirements.

Solid Waste[1028]

III.Q.8 Setting

Collection, Transfer, and Disposal

Municipal solid waste collection, recycling, and disposal within the City is managed by SF Recycling Incorporated, a private company and subsidiary of Norcal Waste Systems, Incorporated. Residential and commercial solid waste generated at the Project site is collected by Sunset Scavenger Company, which delivers it to the SF Recycling Center. There, the solid waste stream is sorted to remove recyclables and organic materials. Organic waste is sent to the Jepson Prairie composing facility, which has the capacity to process approximately 300 tons per day, or approximately 5,200 tons of food waste (food scraps) from commercial premises and 2,000 tons of green waste per month.
